Introduction

The main aim of this booklet is to exemplify standards for those teaching Cambridge International AS and A Level Economics (9708), and to show how different levels of candidates' performance relate to the subject’s curriculum and assessment objectives.

In this booklet a range of candidate responses has been chosen as far as possible to exemplify good, average and weak answers. Each response is accompanied by a brief commentary explaining the strengths and weaknesses of the answers.

For ease of reference the following format for each paper has been adopted:

For Papers 2 and 4 each question is followed by an extract of the mark scheme used by examiners. This, in turn, is followed by examples of marked candidate responses, each with an examiner comment on performance. Comments are given to indicate where and why marks were awarded, and how additional marks could have been obtained. In this way, it is possible to understand what candidates have done to gain their marks and what they still have to do to improve their grades.

Past papers and Principal Examiner Reports for Teachers and other teacher support materials are available on http://teachers.cie.org.uk

Teachers are reminded that a full syllabus is available on www.cie.org.uk
Australia and its Northern Territory

The Northern Territory of Australia is a large, sparsely populated area. It relies heavily on tourism, mining, agriculture and fishing. The extraction of oil and gas and the mining of iron ore and bauxite have grown significantly in recent years. Its manufacturing is principally based on the processing of its natural resources.

The Northern Territory government publishes forecasts, which compare the economic prospects of the Northern Territory with those of Australia as a whole. The table below gives extracts from the forecasts in January 2009.

Table 1: Selected economic forecasts for Northern Territory and Australia

* A$ = Australian dollars

Question 1(a)(i)

Calculate and compare the change in the trade balance between 2008–9 and 2012–13 of the Northern Territory with that of Australia.

Mark scheme

Calculate and compare the change in the trade balance between 2008–9 and 2012–13 of the Northern Territory with that of Australia.

Both improved (1), Northern Territory (NT) has an increased surplus (1), Australia goes from deficit to surplus (1), supporting calculation NT A$1454 to A$3193, Aus A$-41 665 to A$12 303 (2)

Comparative points without accurate calculation can be rewarded, but the points must relate to the 'balance', not the change in imports or exports alone.
Example candidate response

Trade balance of Northern Territory (2008)
2 1412 - 2418 = 1956 (surplus)

Trade balance of Northern Territory (2010)
2 6004 - 2811 = 3193 (surplus)

Trade balance of Australia (2008)
2 176016 - 217675 = -41659 (deficit)

Trade balance of Australia (2012)
2 236824 - 224521 = 12303 (surplus)

In Northern Territory there is an increase in trade surplus which shows that there is a positive Balance of Payment in terms of trade as imported Australian goods improved at a greater rate compared to Northern Territory as proved by the figures calculated above. This shows that Australian government had made a significant improvement although Northern Territory also improved but Australia at a greater rate which is due to population.

Examiner comment

This answer gains full marks. The candidate provides an accurate calculation, although it would have been better if the balances had been shown in Australian dollars. It then goes on to make the comparative points that the balances of both areas had improved and that the balance in Australia had improved at a greater rate.

Mark awarded = 4 out of 4
Example candidate response

Trade balance for Northern Territory

<table>
<thead>
<tr>
<th>Year</th>
<th>Exports - Imports</th>
</tr>
</thead>
<tbody>
<tr>
<td>2008-9</td>
<td>4172 - 2718 = 1454</td>
</tr>
<tr>
<td>2012-13</td>
<td>6094 - 2811 = 3193</td>
</tr>
</tbody>
</table>

Exports increased in 2012-13 as compared to 2008-9. Trade surplus.

Australia Trade Balance Exports - Imports

<table>
<thead>
<tr>
<th>Year</th>
<th>Exports - Imports</th>
</tr>
</thead>
<tbody>
<tr>
<td>2008-9</td>
<td>176010 - 217675 = (41665)</td>
</tr>
<tr>
<td>2012-13</td>
<td>236828 - 224521 = 12307</td>
</tr>
</tbody>
</table>

In 2008-9 Australia has trade deficit but increase in exports over imports make trade surplus.

Examiner comment

This answer contains the necessary calculation, but fails to provide any comparative comment. As a result the maximum mark available is two. The question clearly asks the candidate to ‘calculate and compare’. Careful reading of question requirements is essential for maximum marks.

Mark awarded = 2 out of 4
Example candidate response

\[ \text{change in trade balance of the Northern Territory} = (X_t - M_t) - (X_t - M_t) \]
\[ = (6004 - 2811) - (4172 - 2718) \]
\[ = 1739 \text{ m A$} \]

\[ \text{percentage change} \]
\[ \text{change in trade balance for Australia} = (X_t - M_t) - (X_t - M_t) \]
\[ = (236824 - 224521) - (176010 - 217675) \]
\[ = +53,968 \text{ mA$} \]

Both trade balances increased from 2008-9 to 2012-13.

\[ \text{percentage increase for Northern Territory} \]
\[ = \frac{6004 - 2811}{4172 - 2718} \times 100 \]
\[ = 219.6\% \]

\[ \text{percentage increase for Australia} \]
\[ = -29.5\% \]

The trade balance for the Northern Territory will increase by 219.6\% from 2008-9 to 2012-13. The trade balance for the Northern Territory will increase whereas the negative trade balance for Australia will change into a positive one. The percentage increase for Australia will be -29.5\% in 2012-13 as compared to the negative trade balance in 2008-09.
Examiner comment
This candidate provides a very confused calculation. In addition there is no real direct, comparative comment. There is some understanding of the meaning of ‘trade balance’ however and the recognition that in Australia the balance changes from a deficit to a surplus. It was considered to have sufficient understanding for one mark.

Mark awarded = 1 out of 4

Question 1(a)(ii)

Explain why exports and imports are often measured at constant prices. [2]

Mark scheme

Explain why exports and imports are often measured at constant prices. [2]

Constant prices exclude the effect of inflation (1), more accurate in real terms or shows the volume of trade.

Example candidate response

Examiner comment
This answer gains both marks available. The idea of the ‘real growth in the trade balance’ and the fact that inflation distorts the real balance shows that there is clear understanding here.

Mark awarded = 2 out of 2

Example candidate response

Examiner comment
This answer gains both marks available. The idea of the ‘real growth in the trade balance’ and the fact that inflation distorts the real balance shows that there is clear understanding here.

Mark awarded = 2 out of 2
Examiner comment
This candidate gains a mark for the recognition that using constant prices is better because of the distorting effects of inflation and a change in the exchange rate. For a further mark the candidate needed to say a little more on why it was ‘better’. This could have been for example a statement that the measurement was more accurate in real terms or that it would show the changes in the actual volume of trade.

Mark awarded = 1 out of 2

Example candidate response

Examiner comment
This candidate clearly does not understand the idea of ‘constant prices’. An attempt is made to suggest a possible meaning, but with little success.

Mark awarded = 0 out of 2

Question 1(b)

Mark scheme

Explain two additional pieces of information that would be useful in judging Australia’s international financial position.

From net income, net transfers, capital account, financial account, foreign reserves, exchange rate, terms of trade or alternatives, identification (1), plus 1 mark for explanation of identified point (1)
Example candidate response

Australia's international financial position can be judged by the balance of payment account capital and financial section of the balance of payment account, which shows the capital inflows and outflows of the country. How much investment is done by the foreigners and how much investment is done abroad. For example, a Japanese motor car company setting up a factory in Australia or Australian government building a hospital overseas. The capital and financial account consists of direct investment, portfolio investment flows, other reserves, acquisition disposal of nonfinancial and nonproduced assets and capital transfer. Australia's financial position can even be judged by the terms of trade, that is, the rate at which a country exchanges its exports for imports. How the quantity of imports that a country can get by a unit of exports. The formula is of terms of trade is: \[ \text{Index of terms of trade} = \frac{\text{Index of export prices}}{\text{Index of import prices}} \times 100 \]

Examiner comment

This candidate provides two relevant and additional pieces of information that would be useful in judging Australia's international position. Both are explained with sufficient clarity and detail to ensure full marks.

Mark awarded = 4 out of 4
Example candidate response

The terms of trade can be used in the judging the Australia’s financial position. Term of trade is the opportunity cost of imported goods in terms of export so it is the same.

Terms of trade = \( \frac{Price of Exports}{Price of Imports} \times 100 \).

If terms of trade is greater than 100, it is said to be favourable. If terms of trade is less than 100, it is said to be unfavourable.

The current account can also be used to measure the international financial position.

Examiner comment

This candidate identifies the terms of trade as an additional piece of information that would be useful in judging Australia’s international financial position. The answer then goes on to explain how the terms of trade are calculated. This is worth two marks. The second piece of information identified by the candidate is the ‘Current Account’. This fails to score because without elaboration, this is too vague. If the candidate had gone on to identify and explain some items within the Current Account, this would have been acceptable and would have gained further credit.

Mark awarded = 2 out of 2

Example candidate response

The consumer price index shows the rate of inflation in Australia. Inflation have a very important role in the financial position of a country. The consumer price index of Australia in 2008-9 was 167.7 and in 2012-13 was 186.4. The balance of trade can also be used to determine the financial international position of Australia as calculated above in the past (a).
Examiner comment

This candidate identifies the Consumer Price Index and the Balance of Trade as two additional pieces of information. These were not acceptable because both of these were provided in Table 1 and could not therefore be considered as ‘additional’. This was a very common error amongst candidates. The most likely cause of this error was a failure to read the question requirements carefully and many candidates gained no marks here as a result.

Mark awarded = 0 out of 4

Question 1(c)

Mark scheme

Example candidate response

Examiner comment

This concise answer was awarded full marks. The candidate starts by showing a clear understanding of the meaning of ‘real terms’. An accurate calculation is then provided showing that inflation rose by 11.2% whilst nominal earnings rose by 14.6%. This was then followed by the correct conclusion that in real terms the average weekly earnings rose.

Mark awarded = 4 out 4
In the years between 2008-2009, the average weekly earning in Australia was 9.16 A$, which in 2012-2013 increased to 1050 A$. This change shows that as the year progressed, the wage rate which can also per month average weekly nominal earnings increased by 15%.

On the other hand, the average consumer price index shows that during the years 2008-2009, the inflation rate was 6.7% and in 2012-2013, it increased to 86.4%. Therefore, there was a 28% increase in 2008-2013. This shows that prices rose at a higher rate in Australia.

Analyzing the situation of Australia, it can be said that the average weekly earnings in Australia in real terms decreased. This is because as the nominal average weekly earning in Australia in real terms refers to the wage rate related to the average price level in the country. As it is shown in the table, the average price level also showed a rise in the year 2008-2013, therefore the disposable income in real terms decreases over the years. In simple words, it can be said that the amount that people earned was equal to the amount they had to spend or might be spent.
Examiner comment
This answer showed understanding of the meaning of ‘real terms’, but unfortunately the candidate was unable to use the data to perform all parts of the calculation. A mark was awarded for the correct calculation of the percentage change in nominal earnings, but there is no figure provided for the percentage increase in prices. This meant that no conclusion regarding the change in real terms could be reached.

Mark awarded = 2 out of 4

Example candidate response

Examiner comment
This candidate understands the meaning of ‘real terms’ and gains a mark for this, however the candidate’s application and data handling skills are weak. The candidate does not grasp the distinction between absolute figures, percentages and index numbers and fails to gain any marks for the calculation.

Mark awarded = 1 out of 4

Question 1(d)

With the help of the text and the table, discuss the economic outlook for the Northern Territory.
Mark scheme

With the help of the text and the table, discuss the economic prospects of the Northern Territory. [6]

Good prospects: trade in tourism (income elastic), minerals and oil, rising surplus, relatively low inflation rate, higher real wages, growth of working population.
Poor prospects: rise in unemployment, dependence on narrow range of production, variable demand, externalities of tourism and mining, lack of sustainability of natural resources.

For the identification of points that could affect the economic prospects of the Northern Territories (2 max.)

For explanation of why the identified points are relevant to the economic prospects. (2 max.)

For comment on the economic prospects of the Northern Territories, for example a reasoned summary or conclusion. (up to 2 marks)

Example candidate response

The text given above proves that Australia is a developing country and is specialised in manufacturing sectors such as manufacturing such as extraction of oil and gas, mining ores, etc. and Northern Territories also tourism one of the main business (service sector). The table shows growth in trade balance of Northern territory from between 2008-9 and 2012-13. The consumer price index too showed as
upward ship from 164.6 to 180.0 (rise of 9.36%). The actual inflation was forecasted to be 8.0% in 2012-13 compared to 1989-90 (base year) which might decrease country’s economic international competitiveness and attract less inflows from abroad. Inflation rate is considered to be high and people may lose confidence in money, so, govt should take the figure seriously to increase country’s competitiveness. The Northern Territory’s earning in real terms has been forecasted to increase, which could increase marginal propensity to consume import due to high price of domestic goods. The unemployment rose to 5.7% (4.4% rise from 2008-9) which could pressure govt to provide more unemployment benefits, but labour force showed a rise of 9.4% from 2008-9 to 2012-13 which could increase Gross Domestic Product and output of country. Although, high dependence on natural resources will affect Northern territory in long term as the natural resources are scarce and high dependency on them will lead to depletion of resources.
Examiner comment

This answer starts by describing some features of the Northern Territory economy before identifying information provided in the data that would allow a judgement to be made concerning the economic prospects of this area. The surplus on the trade balance, which is expected to grow, is identified. The candidate then provides some inaccurate estimates of the rate of inflation but goes on to explain the dangers of a high rate of inflation. Some good analysis is then provided using relevant economic concepts. The final paragraph provides a valid comment on the danger of the Northern Territories relying upon natural resources which might run out. A rather fuller comment on the future economic prospects of the region would have resulted in full marks for this answer.

Mark awarded = 5 out of 6

Example candidate response

The Northern Territory constitutes a small economy (than Australia). Its main industries lie in the primary sector. The economy relies heavily on agriculture and mining. In other definitions, it could be labelled as a developing economy. According to forecasts and suggested by the text, the mining and extraction industries are growing significantly. In the future, this development could give way to factories and structural changes in the economy likely to shift towards the secondary sector. Balance of Payments are satisfactory under the circumstances, with exports significantly higher than its imports. Inflation is also considerably low and stable. This means risk-taking is encouraged and business owners have confidence in the economy. Employment is low as well; however, the situation might slightly worsen according to forecasts. This may as well be structural unemployment due to businesses moving towards secondary sector industries.
Examiner comment

This candidate identifies and then explains two items of data that could be used to assess the economic prospects of Northern Territory. Good explanations of the inflation rate and the unemployment rate and the significance of each are provided. Marks are lost here however, because there is insufficient attention paid to an assessment of the overall prospects for the region. No comment is provided for example on whether the negative indicators might be more powerful than the positive indicators. This comment might have been supplied in a concluding paragraph in which some evaluative judgement might have been provided.

Mark awarded = 4 out of 6

Example candidate response

Northern Territory as mentioned in the passage is a populated area, which relies heavily on tourism, mining, agriculture and fishing which indicates that it has abundant industries to earn from as well as from the extraction of oil and gas and the mining of iron ore and bauxite. It shows a very well-developed infrastructure of the Northern territory of Australia.

According to the table 1, in 2009-9, it has an excess of exports over imports showing a positive balance of payments. Further ahead in 2012-13 its exports increased well enough and again having a positive balance of payments showing an increase of 173.9 on consumer price index in a
Examining comment

This candidate refers to a very wide range of economic indicators shown in the data. The answer starts with a description of the Northern Territory and then goes on to list the contents of Table 1. The weakness is that none of the indicators are used to answer the question. For example, it is stated that the unemployment rate is expected to rise from 3.7% to 5.7% and that this is ‘worse’ for the Northern Territory. This is clearly the case, but there is no explanation of why this is so. A simple statement that, for example, a rise in unemployment represents a waste of potential output or that the increase in unemployment benefits represents a drain on government finances would have been sufficient for a further mark here. Explanation of the points identified would have allowed an evaluative conclusion to be reached on the economic outlook of the region.

Mark awarded = 2 out of 6
Question 2(a)

Explain the role that a government should fulfil in a mixed economy.

Mark scheme

A mixed economy is based on private ownership, the profit motive, demand and supply etc. with a role for the government. The role is to provide the environment in which the market can operate successfully. This includes ensuring law and order, national defence, property rights and the provision of public goods and desirable merit goods. It intervenes with taxes, subsidies etc. to influence the behaviour of the private sector and markets and achieve a better allocation of resources.

For a definition of the mixed economy (2 marks)
For an explanation of the role of government in a mixed economy (6 marks)
Example candidate response

A mixed economy is a mixture of planned economy and free market economy. A planned economy is run by the government as it solely makes all the decisions. However, in a free market economy, the decisions are taken by the private sector and the market forces such as demand and supply. There is very little government intervention such as to maintain law and order. 2

A mixed economy, being a mixture of both, the extreme economies, involve two sectors only: private sector and the government. Private sector is free to make decisions but government when want or feel the requirement can intervene and alter the actions of the private sector to an extent only. 2

In a mixed economy, private sectors make private goods only. They employ the factors of production according to their wants and decide what to make and for whom to
make themselves. However, their decision is influenced by market structural forces, known as the invisible hand, demand and supply. Their aim is to maximise profit.

If the private sector is exploiting the consumers and charging a high price, government can intervene and apply a price ceiling or if the producers are being exploited then price flooring can be adopted by the government.

Government collects taxes from the private sector and use them to make public goods for the people. The aim of the government is to maximise welfare so it could create job opportunities for the unemployed without putting any pressure on the private sector to employ more workers.

Government can increase awareness of need goods and demand goods and offer subsidies to the producers of need goods to increase their allocation and impose taxes on the demand goods to decrease their allocation.
The government can decide to fix the balance of payments. It has the ability to impose tariffs, place quotas on the imports to improve the balance of payment. The government can also fix the exchange rate for a limited time as it also affects your balance of payments.

If there are high imports, the government can devalue the currency, making it difficult to import and rely on domestic products. On the other hand, if the exports are falling then the government can devalue the currency making your exports cheap and demanded more.

It’s the government’s job to provide the country with law and order, defence. This will make the private sector secure and will concentrate on their production and will feel free to expand.

Most of times, the actions of private sector are not disturbed by the government and feels free to produce what they
Examiner comment

This is a very full answer. The candidate starts by providing a sound explanation of the mixed economy. The answer then goes on to consider a wide range of roles that the government undertakes in a mixed economy. The comment is made that the role of the government is to maximise welfare and various types of government intervention to achieve this are explained. These include price controls, policy concerning demerit and merit goods, the provision of public goods and the need to ensure law and order so that the private sector can operate.

Mark awarded = 8 out of 8
Section B.

2 a) The mixed economy consists of both the market economy and the public sector. The government operates in the public sector, the role of the government is to provide taxes and subsidies, nationalise industries when required, operate through a centralised economy. Provide public goods and prevent market failure through the prevention of externalities by using methods such as regulation and taxes.

The mixed economy also consists of the market economy. The price system and determined this economy as it helps to interpret demand and supply and help also act as a rationing method. The Market economy will usually produce private goods and consists of thousands of firms and millions of households.

So the government has a huge role to play in the command economy of the mixed economy. However, the market mixed economy also consists of the market economy which will usually undermine any government policies.
Examiner comment

This answer starts with a rather uncertain explanation of the ‘mixed economy’. It then continues with a number of reasons for government intervention, which are valid, but left insufficiently explained. The answer ends with a very confused concluding paragraph.

Mark awarded = 5 out of 8
Example candidate response

Mixed economy is defined as an economy which is controlled both by private individuals and by government. It is the most realistic type of economy in today’s world as relying solely on government might make the economy inefficient and private individuals would ignore social costs.

The government should play a vital role in a mixed economy as private individuals just aim at maximizing profit which might mean that they might even provide harmful goods and ignore negative externalities.

The above diagram shows negative externalities. Negative externalities are the harmful third party effect which might arise from business activity.
Governemnt role should be to control the negative externalities and to provide public goods and merit goods which private individuals do not provide as it is not profitable to do so. Government can impose taxes on the goods which create negative externalities.

\[ P \]

\[ Qd \]

Imposing a tax will make the supply curve shift from $S_0$ to $S_1$ and this will raise its price which will discourage people from buying it unless it has inelastic demand.

Government can also keep control on Multinationals which might be running a monopoly and exploiting the consumers. The government can do this by maintaining strict law and order.
Examiner comment

This candidate produces quite a weak answer. There is no clear explanation of the meaning of the term ‘mixed economy’ provided at the start of the essay. The role of the government is considered very briefly and there is a limited range in the reasons for intervention considered. The structure and content of the answer are both limited and a middling mark is the result.

Mark awarded = 4 out of 8

Question 2(b)

Discuss the accuracy of the definition of public and merit goods as ‘goods that must be provided by the government’.

Mark scheme

Public goods are non-rival and non-excludable such as street lighting. Merit goods are goods underprovided by the market system. The consumers lack full information of the consequences of non-consumption. This might include healthcare and pension provision. Although the government provides public goods because it is not possible for the market due to free riders, merit goods are supplied to a greater or lesser extent by private providers. The government also provides other goods and services which are neither public nor merit goods. The definition fits public better than merit goods but is inadequate in itself.

For an understanding of public goods and why they are provided by the government

For an understanding of merit goods and why they are provided by the government

Discussion of the accuracy of the definition.
Example candidate response

Public goods are only provided by the government, example being lighthouse, defence, traffic signals and roads. They have the characteristics of non-rivalry and non-excludability. Non-rivalry means that consumption by one individual does not reduce the amount available to others. Non-excludability means that no one is excluded from the consumption, not even those who have not paid for it.

Public goods are provided by the government as private sector is not willing to produce it. As no one is willing to pay for it due to the non-excludability, there is no proper demand registered thus private sector is not interested in making them. Non-excludability and non-rivalry gives birth to the problem of ‘free-rider’. Thus the government takes the responsibility of
Merit goods are goods which are good for the harm benefit than the consumer realises, thus are demanded less. There are positive externalities associated to them. Examples being education and healthcare.

Merit goods can be provided by the government but even the private sector wills to provide it. This is because there is a proper demand registered to why people pay for these services and these profits can be earned. Unlike public goods merit goods do not have non-excludability and non-rivalry associated to them. If a surgeon is operating a person, the same surgeon cannot operate another person at the same time so non-excludability is not associated to them. If medicines are bought by an individual then the quantity available for others is reduced. What government does is that it increases the awareness.
and allocation of resources needed to provide merit goods.

Initially, the demand for a merit good is represented by 'D' and the supply by 'S'. The government thinks that they should be consumed by individuals more as they are good for them. So the government increases awareness by advertising and the demand curve shifts from D₁ to D₂. This increases the quantity demanded from q₁ to q₂. This tells that before it was under allocation of resources.
needed to produce this. Another method used to increase the needs allocation of resources and the product is to provide subsidies to the producers.

Before the demand had risen to D₂ and now after the subsidy the supply curve shifted to rightwards. This increased the quantity consumed further and the price also came down. Now of meagre goods will be consumed. 5 + 6 + 4 approx max

The government provides the public goods solely and only helps in increasing the allocation of meagre goods. It does not produce them.
Examiner comment

This is an excellent answer. The features of public and merit goods are each explained in sufficient depth. It is clear that the candidate has a firm grasp of each type of good and can distinguish between them. This allows the candidate to consider whether each ‘must’ be provided by the government. The view reached on each type of good is clear and this is confirmed in a brief conclusion.

Mark awarded = 12 out of 12
Example candidate response

A Public good has the features of biena non-excludable, which means once a person has purchased a good other people will also benefit from it and of biena non-rival which means as more people consume the product the benefit provide to those people who consumed the product will not be diminished. A Merit good is defined as something which provides benefit to people any education but they do not possess the right amount of information of these goods.

The government usually provides public goods such as defence as there are not sufficient resources to produce these goods in a market economy. The features of non-excludability and non-rivalry result in the free rider problem which means consumers benefit from those goods that belong to others rather than purchase their own good. This results in insufficient source resources biena devoted to a product and results in market failure. The government will establish regulation to help
Examiner comment

This answer contains evidence of an understanding of the main features of public and merit goods and gains marks for this. It would have been awarded further marks if the question had been answered more convincingly. A crucial point has been missed. This is that the government ‘must’ provide public goods because the free rider problem, which is mentioned by the candidate, means that private firms cannot charge a price and as a result cannot make profits from their provision. A more assured explanation of this point would have meant that the candidate would have provided a much more convincing answer to the question set.

Mark awarded = 9 out of 12
Example candidate response

Public Goods

Public goods are basically those goods which have maintenance qualities in it. It should be non-excludable which means if the person benefiting from it does not have the full amount of the benefits provided to him, economically the good should be non-rivalrous. This means that the type of good which is being provided could not be provided by any other organisation. E.g. streetlights, infrastructure.

On the other hand, merit goods are those goods which are
These types of goods have positive externalities. Excludable means the person paying for the good can exclude others and get benefit alone over time and competition in the market. For example education as the person paying for the good is only benefiting from it.*

But there is another point which are de-merit goods these goods are also excludable and there is competition available. For example smoking e-cigarettes. As the person paying for the pack is able to benefit but in this type of goods there are negative externalities means which have bad effects on the society on the person in long-term.

Above diagram 2 represents the supply and demand of merit goods but because of the lack of awareness population is not attracted towards it and government resources are getting wasted because they are not utilized properly. Diagram 3 depicts de-merit goods of which supply is controlled but demand is getting higher day by day.
Next comes the "goods that must be provided by the government." The authority of providing certain types of goods like defense, infrastructure, and education must be provided by government. As the decisions made for the defense should not get into private hands because of national security. On the other hand, infrastructure should be provided by the public as a whole is benefiting from it as the standard of living is improved which automatically increase the Gross Domestic Product (GDP) of the country more than there is the education which must be provided by government because this which benefit the economy as there will be more educated and educated people. Therefore, the literacy rate of the country will rise there will be more opportunities for jobs, and less crime, and people would have the standard living. This will also raise the reputation of the country as there would be skilled population which could represent the country in abroad.

Little of relevance to be said.
Examiner comment
This is a very poor answer that displays a complete lack of understanding, together with very poor exam technique. The candidate starts by stating that public goods are non-excludable and non-rival. This is correct, but it is clear from the explanation provided of each feature that the candidate has tried to learn these terms rather than understand them. This lack of understanding continues in the candidate’s explanation of merit goods. It is correctly stated that these goods are excludable and that they have positive externalities, but these features are not explained sufficiently, nor are they used to answer the question about government provision. The answer then drifts into irrelevance with an explanation of demerit goods and some quite general comments on the benefits of for example education.

Mark awarded = 2 out of 12

Question 3(a)

Using economic analysis, explain the possible causes of the increase in the sales of electronic goods, such as mp3 players, in recent years. [8]

Mark scheme

Using economic analysis, explain the possible causes of the increase in the sales of electronic goods such as mp3 players in recent years. [8]

Influences have come from both the demand and supply side. Rising incomes, advertising, changing fashion and tastes have increased demand. Innovation, the introduction of new and improved products and the lowering of costs have increased supply. The fall in the price of the goods has resulted in an extension of demand. More are being sold at lower prices.

Understanding the significance of demand and supply Explanation of demand and/or supply changes (up to 3 marks for each factor explained) 2 marks 6 marks
Example candidate response

There has been a massive hype in the production and sales of electronic devices such as phones, mp3 players, iPods etc. There are innumerable reasons for the boom in the electronics industry.

Firstly, it is the taste of consumers that have changed. Earlier tape recorders and CD players used to serve the purpose of an mp3 player but as these are more durable, of better quality and have a much larger storage capacity, there have risen in production to meet the demand of the consumers.

In this modern era, people prefer quality capacity the most which the mp3 players provide.

The increase in the activity of increased capital intensive production methods is another reason for the increase in the sales of such devices. With growing technology, goods can be produced which are much more cheaper, portable and of a very high quality. Firms take advantage of this to produce goods of low price.

Economies of scale such as market funeral etc which enables

The graph shows that the equilibrium is at E with price \( P \) and quantity \( Q \). With the introduction of technology, the cost of production decreases.
Shifting the supply curve from SS to SS, lowering the price and causing the consumer to demand more at Price P₁ with quantity Q₁.

MP3 players: Their substitutes play an important role in this hype. The substitutes for MP3 players are devices such as iPods, iPhones, MP4 players etc. which are significantly cheaper. Everyone listens to music. With the tape recorder outdated, people tend to use these digital devices which are cheaper than their substitutes. An MP3 player costs around Rs. 1,000 - 2,000 while an expensive iPod costs around Rs. 8,000 - 10,000, over 5 times the price.

The graph shows that the rising prices of substitutes cause a rise in demand for MP3 players with original price at P and quantity at Q₁ to move to P₁.

Another reason for this could be the increased spending by the people and the increase in aggregate demand. As people have more money, their demand for luxuries rises, and they buy a margin thus causing situations that are similar to this.
Examiner comment

This is a very good answer that displays a good grasp of the required supply and demand concepts allowing a very successful analysis of the possible causes of the increase in sales of electronic goods. Diagrams are accurate and the examples provided of a possible increase in demand and increase in supply of these products are valid and appropriate.

Mark awarded = 8 out of 8
The demand for electronic goods have caused its sales to rise. The demand of such goods have increased because of competition. The competition between the firms led to a decrease in prices of such goods. The increase in competition might have caused because of increase in demand, as demand curve shift, the prices of the electronic goods rise which invited new firms to enter in the market which eventually increased the supply of such goods.

Initially, the eqi was at point E, then an increase in demand caused demand curve to shift, which increase the price to P1 and increased Q to Q1. Because of higher prices, new firms entered into the market and caused supply to shift to S1 and eqi go to Q2 and price to P2.

The increase in demand might have caused because of decrease in cost of production. The electronics goods are designed in countries like UK and others develop countries, but are sent to 7000 Assembling...
In China, because of cheap labour, the decrease in cost of production might have caused prices to fall which led to an increase in demand.

The increase in the sales might also have caused because of increase in Advertising. The Persuasive Advertising shifted the demand curve of a product.

In recent years, the consumers' preferences and tastes have changed. They are diverted more towards luxuries. So, a change in preference might also have caused demand to shift.

The increase in sales might also have led because of an increase in the income of consumers.

The scale of preference of consumers might have changed, which means that the things which were once called luxuries before might now be necessities for consumers.

needs application to be clearer

\[2 + 8 + 2\]
Examiner comment

This answer contains some quite valid comment on the possible reasons for the increase in sales of electronic goods. Supply and demand curves are outlined and there are suggested reasons offered for shifts in both the demand curve and the supply curves. Some of the explanation provided is incorrect however and fails to score as highly as it could.

Mark awarded = 6 out of 8
Example candidate response

Products are divided into two groups, inelastic and elastic products. Products like electronics such as MP3 players are elastic products. An increase in the elasticity of sales of electronic goods can be due to changes in price and income in price.

Price elasticity of demand measures the degree of responsiveness of quantity demanded towards a change in price - Percentage change in quantity demanded / Percentage change in price

<table>
<thead>
<tr>
<th>Price</th>
<th>Electronic goods demanded</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>100</td>
</tr>
<tr>
<td>8</td>
<td>150</td>
</tr>
</tbody>
</table>

A change in price of electronic goods will increase its sales revenue because with a decrease in demand increases if prices are reduced. In elastic products such situations will occur.

Other factors for increase in sales revenue will be high incomes because consumers spending power will increase and they will demand for luxury.

Income elasticity of demand measures the degree of responsiveness towards of quantity demanded towards a change in income of consumer - Percentage change in quantity demanded / Percentage change in price.
Examiner comment

This is a weak answer. It is poorly focused and contains irrelevant material. The candidate seems aware of factors that affect sales, such as advertising and the price of the product, but there is no development of a supply and demand framework within which the answer can be delivered. As a result the candidate scores for one or two points made in a disorganised framework.

Mark awarded = 2 out of 8

Question 3(b)

Suggest two possible reasons why a government might increase the indirect tax on such goods and discuss, in light of these reasons, the likely effectiveness of such a policy. [12]

Mark scheme

Suggest two possible reasons why a government might increase the indirect tax on such goods and discuss, in the light of these reasons, the likely effectiveness of such a policy. [12]

Possible reasons include raising revenue to finance government expenditure, cutting the purchase of imports to help the balance of trade. It might be argued that the products are demerit goods because of the harm to hearing and disturbance to others. An indirect tax is imposed on spending and raises the price of the good. PED measures the responsiveness of demand to a change in price and affects the impact of an increase in an indirect tax. A tax will best reduce the quantity imported when demand for imports is elastic as there will be a more than proportionate fall in demand. To raise revenue it is better for demand to be inelastic so that the fall in demand is less than proportionate to the price rise. The effectiveness of internalising the negative externality will depend upon setting the tax at the appropriate rate.

For a definition of indirect tax (1 mark)

For an explanation of one reason for an indirect tax and a discussion of ‘effectiveness’ (up to 6 marks with 4 max. if only one element is considered)

For an explanation of a second reason for an indirect tax and a discussion of ‘effectiveness’ (up to 6 marks with 4 max. if only one element is considered)
3. The market trend of goods and services may have shown rapid changes depending influenced by several factors. The market interact by the forces of the demand and supply in the market.

Demand is defined as the quantity demanded of a product that consumers are willing and able to buy at various prices per period of time. Previously, electronic goods have seen a change in trend of demand where 50 years back, electronic devices were seen as luxury goods. Recently, electronic devices are considered as one of the normal necessity goods, especially among the young generation.

There are several factors that affect the change in demand.

Sales of electronic goods. According to the normal law of demand, the quantity demanded will rise as price falls. This is shown by an expansion along the same demand curve and it is solely affected by the fall in price. However, there are other factors that may affect demand. When electronic devices are concerned, the major factors that causes this increase may be the technology and change in consumer's taste in favor of electronic devices. The other reason that contributes may also be influenced from the advertisement by the media. This factor causes a parallel rightward shift in demand curve.

The expansion of demand may also be affected by the price elasticity of demand. The more elastic it is the more significant change may be observed on price fall.
The shift in demand curve as shown by the graph is not affected by the price. But other factors such as trend, consumer price of other goods (substitute and complement), festivals and others.

Analyzing the supply side of the electronic devices, the increase in supply in the market by be significant by the increase in price. This is seen by the expansion of supply curve as demand increases. This is because a rise in price may be a form of incentive for producers to produce more.

As price rise supply expands despite there is a fall in demand.
Supply too may shift leftwards due to other reasons other than price. There may be a development in technology that occur in the electronic device market for instance, that causes supply to shift right. Supply defined as the quantity of a good that producers are willing and able to supply at various prices for a period of time. The price at which consumers purchase.

At point A, the initial equilibrium of the demand and supply which may be 50 years back when technology was not well developed. But as technology changes and advanced and the fine consumer preferences favour the electronic devices, there is an increase in both demand and supply. Thus, a new equilibrium formed at point B. Despite the shift in both curves, the price remain unchanged as it is proven there are other contributing factors other than price that affect the sales of electronic goods. This may be due to change in technology mainly and the change in consumer tastes. Government also contributed in this drastic evolution. Another factor from the supply side was that affect the demand is the business strategy and management. For example, the new CEO of Apple corporation had managed to boost the sales of Apple product a few times more than previous years. Government policy to encourage the usage of technology also contributed to the increase in sales of electronic
Examiner comment

This candidate clearly identifies two reasons for the imposition of an indirect tax. Each is explained clearly. Although the second reason identified has the effectiveness of the tax examined, the first reason does not consider this aspect of the question. The question clearly states that effectiveness should be considered, so marks are lost and the mark awarded less than it could have been.

Mark awarded = 8 out of 12
Demand pull inflation is a major reason. It is defined as the rise in demand for goods which causes the prices to rise. This is when too much money chasing too few goods with a large amount of money in the hands of people. Their demand for luxury tends to increase. This hype in the buying of unnecessary items causes the prices to rise thus resulting in inflation. With the introduction of a new product, the prices of such goods increase. The cost of production causes the producers to reduce their supply that causes a rise in price thus lowering their quantity demanded. In addition to this, the price rises the quantity demanded decreases. The people who still continue to buy such expensive luxuries pay large sums of tax to the government which adds to their revenue which can be spent on economic...
The graph shows the original quantity demand equilibrium at E with price P and quantity Q. As a tax of xy is imposed the price rises to P1 reducing the quantity demanded to Q1. As the demand is inelastic most of the tax (xy) is borne by the consumer and y by the producer.

A balance of payments trade account deficit is another major reason. The trade account comprises of all the visible and invisible imports and exports of a country. High quality goods produced in foreign countries are cheaper and of a better quality people tend to try import the goods rather than consuming the local production. The increase in unnecessary import causes a balance of trade deficit leading to a balance of payment deficit thus depleting the countries foreign reserves. This causes depreciation of the country's currency.
The currency leading to unemployment, inflation et al. Hence, by taxes, the prices rise causing the demand for goods to decrease. Those who still consume pay taxes to the government increasing their revenue, making economic development possible.

The graph shows the impacts and exports are getting affected. The gap between demand and supply is filled through imports with a tax of ef. The demand for imports falls to xy. This is due to rising prices.

Hence the imposition of taxes will cause a major effect on the economy. It will benefit it, making the economy prosperous.

\[ 1 + 1 + 3 = 5 \]
Examiner comment

Candidates were asked to identify two possible reasons for the imposition of an indirect tax. This candidate is unclear on the possible reasons. The reference to demand-pull inflation is confused. There seems to be a recognition that indirect taxes can raise revenue, but this is not developed. Similarly, the explanation of a trade account deficit is not fully clear. In terms of effectiveness, it is correct to refer to the price elasticity of the taxed profit, but this candidate does not apply the concept successfully. The answer also fails to define or explain, ‘indirect tax’.

Mark awarded = 5 out of 12
Example candidate response

The Government might increase indirect taxes due to following reasons:

i) To decrease the demand of such goods.

ii) To prevent itself from budget deficit.

By increasing the indirect tax on firms producing such goods, firms may pass this tax to the customer and may charge high prices and hence it will reduce demand; however it also depends on the elasticity of demand of that particular good. If the good has elastic demand a small increase in price will lead to a large decrease in quantity demanded and if the product has inelastic demand a large increase in price will lead to a small increase in quantity demanded. The likely effectiveness of such a policy can be increasing investment as fewer amount of money will be spend on luxury items or this may increase the saving depending on the interest rate.

![Diagram showing supply and demand curves with price changes and quantity adjustments.](image-url)
The increase in indirect tax may result the individual with the higher disposable income at the end of month. As fewer amount of money will be spent on luxury items and this may lead to better standard of living. By increase the tax it also provides more equal distribution of income.

The govt may increase indirect taxes in order to achieve prevent it self from budget deficit. By increasing the indirect taxes it will limit the wants of consumer and this will reduce the aggregate demand of consumers which means imports are less and exports will be high. As well as budget and this will result in budget surplus. However, in a long run, currency of the country may depreciate. Because continuous budget surplus will make the exports expensive for all exports expensive and imports will be less expensive which will result in depreciation of currency.

Mark awarded = 3 out of 12
Question 4(a)

Explain why the successful operation of the division of labour depends upon the use of money. [8]

Mark scheme

Explain why the successful operation of division of labour depends upon the use of money. [8]

Division of labour involves dividing the production process into a series of stages. This leads to more specialised outputs which are not necessarily final products. Trading these in a barter system would be difficult, inefficient and probably impossible. Money, anything that is generally acceptable as a means of payment, can act as a medium of exchange and a unit of account, so enabling trade to take place and making division of labour effective.

Understanding of division of labour and money 4 marks (one only 3 max.)
Explanation of the link between the functions of money and trade 4 marks
Modern day production is based upon the principle of division of labor. Division of labor is a process which is accompanied by specialization where the workers do that task they are good at. This is time saving and efficient. The division of labor has been further promoted by the use of money as a medium of exchange.

In old times when the concept of money was not introduced people used to rely on barter system to carry out their daily transactions. A farmer would take his sack of wheat and go into the market to buy some bread in return. Barter was risky and time consuming and depended upon the double coincidence of wants. It discouraged division of labor and specialization because people only exchanged complete goods e.g. A person who specialized in making wheels couldn’t exchange them for a sack of wheat; he would only get wheat if he had a whole cake and not just the wheels. Thus barter discouraged division of labor.

With the advent of the use of money as
The medium of exchange the concept of division of labor became more common. A chair manufacturer who used to make 5 chairs a day now made 20 chairs a day by employing division of labor. Workers can now do the tasks they are best at and get paid for them.

Successful operation of division of labor depends upon the use of money because money makes the process of economic transactions smooth by eliminating the double coincidence of wants. The employer does not have to pay his workers different commodities eg. division of labor was in basics the employer would have to reward one worker with wheat, the other with rice and so on. Whereas, now with the general acceptability of money workers can be paid simply in money because it is now a medium of exchange and a unit of account and they can buy the commodities they desire what they earned.

Also the use of money as a measure of money has allowed employers to objectively measure the productivity of labor in monetary terms whereas this before this was not possible.
Examiner comment

This candidate explains both the division of labour and money as a medium of exchange. The answer goes on to explain how money facilitated exchange through the removal of barter and the necessity of a double coincidence of wants. This encouraged growth and the division of labour. Each concept together with the link between them is explained ensuring full marks.

Mark awarded = 8 out of 8
The use of money has a significant impact on the successful operation of an economy. Money is a medium of exchange, a method of account and a store of value. Within the economy and in the international sector, the exchange of goods and services takes place using money. Labour is a factor of production and is very vital for production in an economy. All economies benefit from the factor endowment and the amount of resources they have for production of goods. This benefit that the economies derive can be maximized if resources are used in a way that they are best suited for and this leads to specialization.

Division of labour is a part of specialization process to increase the productivity and thus the benefits derived from it. This also contributes to an efficient use of resources present in an economy, as less resources are now wasted. Specialization has benefits both domestically and internationally. When looking from the domestic point of view, the production process increases and so does the productivity when labour is specialized. Productivity refers to the output per worker per given resources per time. For a manufacturing industry, for example, if all workers work together at all stages, the process would take much longer time compared to each worker doing his designated task. Division of labour...
also leads to labour efficiency. An old saying states that too many cooks spoil the broth. Same is the case here. If all of the work force works at each stage together, problems arise and this may affect the quality if not the quantity of the product produced.

For the international sector, the concept of division of labour and specialization is rather a vast one. This takes into account the whole country specializing to produce goods that the resources of the country are best suited for. This increases the benefits from trade and also the efficiency as less resources are wasted. This phenomena can be explained using the comparative advantage theory. For two countries with fixed amount of resources, the resources might be well suited for producing one good in the market and not the other. Take for example manufactured goods and agricultural goods. Since opportunity cost ratios differ between the countries, it will be well suited for both countries to specialize in the production of the best suited good and then trade with each other to maximize the benefits. Comparative advantage is shown in the graph below.
Examiner comment

This candidate explains in some detail the division of labour and identifies this as an aspect of specialisation. Money is also identified as a medium of exchange. This scores highly. Unfortunately, the candidate scores very few marks for the second part of the mark scheme. There is very little on the link between the use of money and the growth of the division of labour and trade.

Mark awarded = 5 out of 8
Example candidate response

Examiner comment

This is a very poor answer that does not go far beyond a very basic grasp of the two central concepts. The candidate gives a very brief definition of the division of labour but there is little accompanying explanation or attempt to illustrate the process through examples. The answer also contains some irrelevant comment on the disadvantages of the division of labour. This is followed by a list of the functions of money. Again this is far too brief. The candidate fails to display any idea of the link between the two concepts.

Mark awarded = 3 out of 8
Question 4(b)

Discuss whether it is the behaviour of producers, consumers or governments that is most likely to cause inflation.

Mark scheme

Discuss whether it is the behaviour of producers, consumers or governments that is most likely to cause inflation.

Inflation is a sustained rise in the general price level and is measured by the CPI or RPI. Each of the groups can contribute to inflation although in different ways. Producers may increase prices to raise profit levels or to respond to higher import prices (cost push); consumers may increase their spending and reduce their saving raising AD (demand pull); governments may increase the money supply (monetary inflation), lower direct taxation and run budget deficits (demand pull) and raise indirect taxation (cost push inflation); they may also manipulate the exchange rate. Candidates can argue for any group although government influence may be most widespread.

For a definition of inflation
For an understanding of different types of inflation
Analysis of the influence of different groups
Discussion of the relative impact of the groups

1 mark
6 marks
6 marks
4 marks

\( \text{(10 marks max.)} \)
Inflation is a persistent rise in general price level. Inflation can be of different types:
1) Galloping inflation (5% - 10%)
2) Walking inflation (10% - 15%)
3) Hyper inflation (1000% and 10000%)
4) Creeping inflation (1% - 5%)

Inflation causes general price level to rise, which can eventually cause money to lose its value. Inflation can be due to behaviour of producers (cost push inflation) or government (monetary inflation).

Demand pull inflation occurs when aggregate demand in the economy rises due to increase in consumer spending, increased government spending on merit goods, low interest rate resulting in capital investment. All these will result in increase in aggregated demand in an economy, too much export earning and little import payment technological growth resulting in more production.
Increase in aggregate demand will result in increase in price level along with increase in national income. However, this is only a passively uphill point of full employment after which increase in aggregate demand will increase price level but not national income. Demand pull inflation is due to pattern of spending of consumers.

Cost push inflation is initiated by rising price and sustained by rising price of goods. Cost push inflation can be caused by:

1. Increase in price of raw materials (expensive cost of production).
2. Increase in wage rate (trade union).
3. Increase in price of imported raw material caused by increase in prices in other countries.
4. Most increased e.g. indirect taxes.
These will result in increased cost of production and decrease in profit margin for producers who will cut back on the production and supply of goods.

A decrease in supply has caused rise in price level and fall in National income and employment. When inflation and unemployment coexist, they are called stagflation. This type of inflation is caused by production patterns of producers.

Monetary inflation, monetarist believe that inflation is only caused when government allows too much money supply in an economy.

According to the theory of Monetarism:

\[ M \times V = P \times T \]

where:
- \( M \) = supply of money
- \( V \) = velocity of money circulation
- \( P \) = price level
- \( T \) = quantity of goods and services
Monetarists believe that rate at which money changes hands is fairly constant. Hence $M \times P$

The price level is directly proportional to supply of money that the govt allows. Increase in supply of money will result in increased spending. Aggregated demand rise, increased aggregated demand will cause prices to rise and eventually causing cost push inflation. Hence they claim that the only reason of inflation is money supply in an economy.

In conclusion, I would say that inflation is caused by different behaviours of all three: producers, consumers and government. Different patterns of sales and purchase and government policy interact to cause general price level to rise in an economy.

Mark awarded = 12 out of 12
Example candidate response

b) Inflation means the continuous increase in the price levels of goods and services in the economy over time. There are three causes of inflation: demand pull inflation, cost push inflation, and money supply inflation.

Demand pull inflation is when the total demand of goods and services increase a lot, the prices of goods and services increase and then it cause the demand pull inflation. It is the behaviours of consumer to cause inflation. The inflation will cause the cost of living increase and the living standard decrease of people. Also, the unemployment will increase. The government will using laws such as indirect goods tax on goods, especially the goods will inelastic demand and elastic supply, then
people will pay more tax and the consumption will decrease, and the demand of goods and services will decrease.

Cost push inflation is when the cost of production of a good or service is very high, then the producers will increase the price to gain more profit. Then it will cause the cost push inflation. It is the behaviour of producers to cause the inflation.

The inflation will high domestic inflation will cause the exports more expensive and imports more cheaper, then people will prefer to buy the imports instead of local produced goods. The local companies may fail. To solve this situation, the government will give a subsidy to producers to encourage the production and using the tax the the cost will decrease and the price will decrease, the inflation will reduce.

Money supply is the government gives money to the consumers to encourage the consumption. It will cause the demand of goods and services increase and the prices increase. Then it will lead to an inflation. It is the behaviour of the government to cause the inflation. The high domestic inflation will cause the exports less competitive, then the demand for exports decrease and the demand for imports increase, it might lead to a balance of payment deficit for the country. Then the government will take some actions to deal with balance of payment deficit and the inflation. The government may use the expenditure switching policy to reduce the bop deficit that is switch the expenditure on imports to the local produce companies.

Overall, I think the behaviour of producers, consumers, producers and governments will cause the inflation.
Examiner comment

The candidate starts with a definition of inflation. This gains some credit. The answer then lists and gives a brief explanation of demand-pull, cost-push and monetary explanations of inflation. Each is generally satisfactory, although lacking in depth and reference to economic frameworks. These gain credit, but the main weakness of the answer is the limited focus on the behaviour of producers, consumers and governments. This means that a full discussion of which is most likely to cause inflation is not provided and this leads to the very weak conclusion and a disappointing mark.

Mark awarded = 7 out of 12

Example candidate response

Inflation is a general and persistent rise in price levels of all goods and services. Inflation can be caused by demand pull, cost push inflation and monetarist view.

Our government, producers and consumers all have to pay and cut down, the rate of inflation. Government could remove import taxes and so people would have an increase in income, leading to demand pull inflation. They could allow unlimited printing of money, supplying excess money to people, leading to inflation. According to the monetarist view, they could lower interest rates as well.
If the government starts encouraging borrowing and lending at rates from banks that will increase demand pull inflation, its direct taxes could be removed or lowered leading to cost push inflation.

Policies could encourage inflation if they start using capital intensive methods which will lead to unemployment.

![Production possibility curve]

**Inflation Rate %**

**Unemployment Rate**

The above diagram is an production possibility curve showing the rate of inflation and unemployment reaction.

If producers start giving up and stop producing goods in their country this will make companies rely more on imports causing a balance of trade and causing inflation. However, should give more importance to home-produced goods.

Therefore from the above possibilities it can be concluded that causing production and government to cause inflation but they are not the only reason. Inflation decreases in countries from abroad if our country can be made to be competitive by increasing the value of money led to be controlled.
Examiner comment

This candidate is aware of how the government might cause inflation, but this is presented as a few isolated points and is not developed within a conceptual framework. Similarly, reference is made to producers and consumers, but without the conceptual framework, the candidate is unable to develop the answer to gain a good mark.

Mark awarded = 5 out of 12
Emerging economies and the way out of a recession

During the recession of 2009 several economists forecast that some emerging (fast developing) economies would perform better than the developed economies. One indicator of this, they said, was the strength of the exchange rate of the currency of some emerging economies against the US dollar. For example, between November 2008 and July 2009, the Brazilian currency rose 11.4% against the dollar and the Indonesian currency rose 10.2%. Another indicator was the forecast growth rate in GDP as shown in Table 1.

</table>

Emerging economies are often dependent on exports to achieve an increase in GDP. Some economists suggested that it would be better for their economic growth if these countries were to concentrate on domestic demand rather than exports.

China, in particular, they said could lead the world out of the recession if it relied increasingly on domestic demand. Indeed, the Chinese government encouraged a shift from export-led industries to programmes aimed at improving the Chinese infrastructure in order to create jobs and thus increase consumption of Chinese goods. Banks were encouraged to make borrowing easier in order to create more credit for consumers and businesses. The government started a massive fiscal stimulus and increased its forecast of GDP to a growth rate of 8.3% in 2009 and 10.9% for 2010 (previous forecast figures were 6.0% and 7.0% as in Table 1).

However, other economists do not accept that there should be an emphasis on domestic demand. They argue that trading links are the strongest evidence of the emerging economies’ ability to grow. They state ‘no emerging market that adopted an export-led growth model has subsequently needed to break away from it – including China’. China’s exports as a percentage of GDP are 32% compared with only 13% for the US. Smaller Asian countries are even more dependent on exports; Singapore’s ratio of exports to GDP is 234%, Hong Kong’s is 169%. It will be difficult for economies such as these to increase domestic demand and reduce their dependence on export-led growth.

(Source: Financial Times: June 12 2009. Table source: Economist p105 April 18–24 2009)
Question 1(a)

Explain what is meant by GDP. [3]

Mark scheme

The Gross Domestic Product (GDP) measures the value of economic activity within a country. Strictly defined, GDP is the sum of the market values, or prices, of all final goods and services produced in an economy during a period of time. (For stating Gross Domestic Product 1 mark only) [3]

Example candidate response

Examiner comment

This candidate had an understanding of the meaning of GDP, and stated that it was for a given time period and expressed as a monetary value.

Mark awarded = 3 out of 3

Example candidate response

Examiner comment

This candidate gave an explanation of GDP but omitted to state it was for a given period.

Mark awarded = 2 out of 3
Example candidate response

GDP stand for gross domestic product. It determine a high country with high GDP is usually a rich country, while country with low GDP tend to be poor country. GDP shows the good and

Examiner comment
This candidate gave a poor explanation which did not include any reference to monetary value nor to a time period.

Mark awarded = 1 out of 3

Question 1(b)
The article says that banks were encouraged to make borrowing easier. Explain what this might mean and why the government might have thought this was necessary. [3]

Mark scheme
It means more available credit, easier to get; or credit at lower interest rates. This would be likely to increase national income by the multiplier process. (A descriptive reference to the process is sufficient; there is no need to use the actual term) [3]

Example candidate response
The statement means that the banks would allow individuals and firms to borrow money more easily by lowering the interest rate. This would allow more credit for consumers and businesses and hence increase domestic consumption and investment. Since consumption and investment are components of the GDP, the GDP would thus increase indicating economic growth.

Examiner comment
This candidate clearly explained the meaning of the phrase and the reason why easier borrowing might be necessary to stimulate economic growth.

Mark awarded = 3 out of 3
Example candidate response

(b) In a period of recession, the consumption level goes down. Store of saving is being done. As they are in a period of recession, unemployment is high. So encourage borrowing from bank, will lead to investment in the country where employment will increase, when the employment will increase then they will be more consumption. Thus little by little it will be the way out of recession.

Examiner comment

This candidate attempted to answer the question but the answer did not direct itself explicitly to the phrase which should have been explained. Instead the answer began by describing what happens to consumption in a recession.

Mark awarded = 1 out of 3

Example candidate response

(b) In order to create more credit for consumers and business, the government started a massive fiscal stimulus and increased its forecast of GDP to a growth rate of 8.2% in 2009 and 10.1% for 2010. This means with the bank borrowing they had been a marked increase of 8.6% in GDP.

Examiner comment

This candidate mentioned credit but did not answer the question about what the phrase meant nor why the government might wish to increase credit.

Mark awarded = 0 out of 3
Question 1(c)

Is there enough evidence in the article to support the view that there has been an improvement in the economic situation of emerging economies? [6]

Mark scheme

Use the figures for specific exchange rates, and figures for GDP – expect to see examples of emerging/developing countries compared with developed countries. But they are only selected countries, and for only two years and they are projections not actual figures. Exchange rate figures may mean exports become more difficult to sell. [Maximum 4 for one side of the argument only]

Example candidate response

c) The table 1 shows future growth rate in GDP of different countries in which all the emerging economies have an increase in their GDP. Also the article says that the exchange rates of emerging economies increased with respect to US.

However, increase in GDP does not show that the economic situation has become better. Due to
- population: a greater rise in population than GDP means that economic situation is worsening.
- inflation: rise in GDP may have caused demand pull inflation so the rate of inflation is high.
- Quality of life: increase in GDP does not tell us about the quality of life.
- Unemployment: may have increased due to rise

So, there is evidence not sufficient evidence to support the view that there has been an improvement in economic situation of developing economies.

Mark awarded = 4 out of 6

Examiner comment

This candidate used the information in the article to illustrate an improvement in the economic situation of the countries but also suggested reasons why this information was not sufficient to draw a definitive conclusion.
Example candidate response

No, there is not enough evidence. It is stated that emerging economies are often dependent on exports to achieve an increase in GDP, but no exact evidence is given. Besides, exchange rate figures of the currency for other emerging economies against the US dollar are not given, only figures of Brazil and Indonesia. An indicator was not enough to show an improvement.

Examiner comment

This candidate mentioned that emerging countries are often dependent on export-led growth and did suggest that the information about this was not sufficient to indicate whether there had been an improvement in their economic situation. However, there was no mention of other indicators which might prove useful, nor much mention of other information in the article.

Mark awarded = 2 out of 6

Example candidate response

(c) No. There was no evidence shown on the rate of inflation in each country. An increase in inflation will lead to an increase in prices of goods and services. Inflation will tend to increase the GDP of a country. A country with high inflation such as Japan will show a faster growth rate in GDP compared to a country with lower inflation rate such as Indonesia. There was also no evidence shown on the balance of payment of each country. Some countries rely on exports for economic growth while some rely on domestic demand. The balance of payment of a country will show the reliability of exports in order to allow economic growth.

Examiner comment

This candidate wrote about the level of inflation and the balance of payments. Although these two indicators might be used to consider whether there was an improvement in the economic situation of a country they were not relevant to the article given in the question which did not contain any statistics for these indicators.

Mark awarded = 1 out of 6
Question 1(d)

Identify the two policy approaches suggested by economists in the article and discuss whether there is a conflict between them. [8]

Mark scheme

An increase in domestic demand to encourage growth and export-led growth. 2 marks
Conflict? Different approaches but same aim of growth 2 marks
Increase exports improves balance of payments and increases injections and GDP; increase domestic demand will also increase injections and help increase GDP. No conflict. 2 marks
Increase domestic demand may increase incomes and increase imports which may need to be offset by further export growth. A possible conflict. 2 marks

[A general description of fiscal and monetary policy; 2 maximum]

Example candidate response

The first policy approach suggested by economists is growth by increased domestic demand, which was utilised in China in order to improve Chinese infrastructure and create jobs, thus increasing the consumption of goods. The second policy suggested is the growth by exports. They state that developed economies, emerging economies such as Hong Kong and Singapore have an extremely high ratio of exports to GDP and are heavily reliant on exports to achieve economic growth.

A conflict exists between these two growth-achieving policies. If an economy were to adopt a domestic demand based policy, it would have to impose protectionism measures to prevent imports from competing with the sale of domestic goods. This could potentially reduce future international competitiveness of that country if the domestic firms take advantage by hiding behind these measures and not expand. Conversely, a country that relies heavily on exports to grow can face a shortage in the domestic market if goods are exported excessively. Furthermore, the revenue generated by these goods depends on the elasticity demand elasticity of the goods.

However, the conflicts between the two policies can be nullified if a government strikes the right balance between the two policies. It is possible to export in large quantities yet be able to provide enough protectionism to allow local industries to expand and become a competitor in the international market in the future.
Examiner comment

This candidate identified the two policies mentioned in the article as the need to support an increase in domestic demand or the need to support export-led growth. The answer was then directed to the second part of the question which asked whether there was a conflict between the two aims. Although there was a statement in the last paragraph which refers to a way to lessen any conflict, the answer could have been improved by further comment on the possible similarities between the two policies.

Mark awarded = 6 out of 8

Example candidate response

Examiner comment

This candidate’s main emphasis was to say that the two policies were fiscal and monetary policy rather than that which is in the article which are a decision to concentrate on domestic demand or on export-led growth. However, the answer did try to relate fiscal and monetary policy to domestic demand and export-led growth so there was some relevant material in the answer.

Mark awarded = 3 out of 8
Example candidate response

(a) The policy approaches suggested by economists are expansionary monetary policy and contractionary monetary policy. During recession, expansionary monetary policy will cause a decrease in interest rates. This will cause an increase in investment, economic activity will increase, unemployment will decrease which lead to an increase in price where inflation occurs.

decrease in cost of borrowing which allow income of consumers to increase. When income increases, aggregate demand will increase leading to an increase in price. This will cause inflation. During inflation, contractionary monetary policy will increase interest rates. An increase in interest rates will cause an increase in cost of borrowing which allow income of consumers to fall. This will cause aggregate demand to fall leading a decrease in price. When prices of goods and services decrease, economic activity will fall which leads to unemployment. In expansionary monetary policy, unemployment is cured, however it leads to inflation. In contractionary monetary policy,un inflation is cured, however it leads to unemployment. Therefore, there is a conflict between the two policies.

Examiner comment

This candidate wrote about contractionary and expansionary monetary policy. The answer bore little relation to the information in the article which considered the wisdom of supporting an increase in domestic demand against an increase in export-led growth.

Mark awarded = 1 out of 8
Question 2

The use of cars causes market failure. To achieve an efficient use of resources it would be better if governments intervened to affect both the production and the use of cars.

Explain the meaning of the terms ‘market failure’ and ‘the efficient use of resources’ and analyse whether economic theory can be used to support this argument. [25]

Mark scheme

Candidates need to explain the two terms, market failure and the meaning of the efficient use of resources, and then consider the argument. Market failure can be explained by reference to possible excessive profits, the need for very large investments, the existence of externalities and of merit goods, and of the need for public goods. Economic efficiency should be explained in terms of productive and allocative efficiency.

Government intervention can be through regulation, taxation or subsidies.

There are negative and positive externalities from car use. Negative externalities include pollution. Positive externalities include less crowded public transport with greater comfort; benefits from the expenditure of the tax receipts. Unlike other positive externalities where subsidies have been used, it has never been suggested that subsidies ought to be used to increase the positive externalities from private car use. Any subsidies given are used to make alternative public transport more attractive. However, taxes have been used to decrease negative externalities. Taxing the use of cars is usually presented in the context of negative externalities to achieve allocative efficiency. Taxing production might not result in productive efficiency. [25]

L4 For a thorough explanation of both efficiency and market failure and a competent discussion of the role of the government in promoting efficiency overcoming market failure. A reasoned conclusion should be presented [18–25]

L3 For a competent explanation with either a more limited comment on both efficiency and market failure (perhaps concentrating on productive efficiency) or a full explanation of one but little comment on the other. The role of the government will be discussed in a more limited way but a conclusion should still be presented. [14–17]
(L3 maximum if there is no mention of production and use of cars)

L2 For an undeveloped explanation of efficiency/market failure with very little discussion of the role of the government. Mention of the government will be descriptive rather than in the form of a discussion related to efficiency/market failure. It is likely there will be no conclusion. [10–13]

L1 For an answer which shows some knowledge but does not indicate that the question has been fully grasped, or where the answer contains irrelevancies and errors of theory. [1–9]
Cars are modern means of transport and it is inevitable that everyone relies on it to travel from one place to another. However, production and usage of cars may not be beneficial to the whole economy as it causes pollution and depletion of natural resources. There will be market failure and inefficient allocation of resources.

Market failure refers to an inefficient allocation of resources where there exists negative externalities, under-provision of merit goods, non-provision of public goods and even imperfect markets. Negative externalities include pollution and traffic jam. Under-provision of merit goods exist due to lack of information, while public goods are not provided because of free rider problem. Free rider problem means a situation where nobody is willing to produce a public good for the benefit of the whole economy. Imperfect markets are markets which do not produce at allocative and productive efficient rates.

Efficient allocation of resources include allocative efficiency and productive efficiency. Allocative efficiency occurs when price equals marginal cost, which means there is production of goods and services according to demand and supply of the economy. Productive efficiency occurs when price equals to minimum average cost where production takes place at its lowest cost. In other words, efficient allocation of resources refers to an economy producing at its production possibility curve (PPC) and the three economic problems of for whom to produce, how to produce and what to produce have been solved.
At point A, there is an under-utility of resources and production is inefficient. At point B, there is efficient allocation of resources and at point C, there is not enough resources to produce at that point. Production is unattainable.

Allocative efficiency is where \( P = \text{minimum AC} \)

If production is at X, then productive efficiency is not achieved and output has to be increased and price lowered so that cost of production is at minimum AC. If it is at Y, then price has to be lowered and output decreased.

Allocative efficiency is where \( P = MC \) (marginal cost).

The point where P equals to MC is allocatively efficient and points a and b are not allocatively efficient. Price and output at b is too high whereas
However, according to principle of Pareto optimality, Pareto efficiency states that when someone is better off, another will be worse off. For example, when John is able to enjoy more goods, Ali will be worse off than before. Therefore, government intervention may be necessary to achieve allocation of resources.

Ways of government intervention in production and use of cars include regulation and taxes etc. The government intervenes so that pollution caused by usage of cars is reduced. Methods of intervention include imposing road tax. For example, Malaysian government have increased the amount of road taxes and price of tolls to discourage frequent use of cars and encourage the use of trains and other public transports so that air and noise pollution can be reduced. Air pollution is a form of negative externality.

In the diagram above, when road tax exists, the supply of car will decrease as cost of using cars have increased. Therefore, the quantity of cars on the road will decrease from Q₁ to Q₀ and cost of using cars increase from P₁ to P₀. However, government intervention can cause deadweight loss as shown in the shaded region. Deadweight loss are loss in potential welfare of consumers.
The government should also intervene so that there is no exploitation of natural resources in production of cars. This means that it would ensure that the current and future generations are able to consume enough resources. The government sets regulations in production of cars such that only firms which obtain approval and licences from the government are able to produce cars. For example, the government of Malaysia only issue licences to Perodua and Proton to fix production of cars. However, this will cause imperfect market structure where only two large firms are involved in production of cars, i.e. oligopoly market will exist and monopoly market will exist and consumer welfare may be compromised due to high prices and low output of a duopoly firm. The working of the ‘invisible hand’—price mechanism will also be affected.

Besides, the government intervenes so that quality of cars produced are high and consumers are not exploited. This is because consumers usually lack complete information when buying cars. So, the government monitors the production of cars by carrying spot checks in car factories. The government also made it compulsory for car manufacturers to do multiple test runs before launching the product so that money spent on buying cars are worth it. For example, Toyota company, the Malaysian government sends officers to do spot checks in car factories so that there is not production of cars are smooth and there are no faulty engines being used in production. However, implementation of there may be loopholes and transparency problem as some enforcement officers do not carry out the duty properly.

As a conclusion, government intervention is necessary to reduce market failure. However, it does not mean that there will be a perfect allocation of resources and
Examiner comment

This candidate gave a good answer which referred to both the analytical theory of market failure and to the application required in the question relating to cars. A reasoned conclusion was presented. The answer fell within the band 18–20 in the general comments at the start of the mark scheme.

Mark awarded = 20 out of 25
Market is considered to be fail when there is non-provision of public goods, under-provision of merit goods and over-provision of demerit goods. Externalities are the cost or benefit incurred by a third party of a production or consumption of a good or service. There are two types of externalities, namely positive externalities and negative externalities. The use of cars are known as negative externalities. Negative externalities occur when marginal social costs (MSC) exceed marginal private costs (MPC). As the good is produced more than the socially optimum level, it is said to be overproduced and this causes a low price the good. The use of cars are said to be negative externalities as a car emits carbon monoxide into the air, which causes air pollution. The third party will incur the external cost. Marginal social costs can be found by adding marginal private cost with marginal external costs.

Economic efficiency can be achieved when there is productive efficiency and allocative efficiency. Productive efficiency occurs when goods and services are produced at the least possible cost. Productive efficiency can be achieved by producing goods and services on the lowest possible cost which is $AC_1$. Secondly, it should produce on the lowest point of the lowest average cost curve. This is known as technical efficiency. Productive efficiency can also be achieved by producing...
goods and services right on the production possibility curve. The diagram below shows that point X is productive inefficient as the resources used can produce more goods. Point Y shows that it is productive efficient as resources are fully employed.

Competition allows productive efficiency to occur as firms will produce goods at the lowest possible cost. In perfect competition, productive efficiency is achieved.

Allocative efficiency occurs when the right products are produced with the right amount of resources. Therefore allocative is achieved when price is equal to marginal cost (P = MC). When goods are produced at 2 units, it is allocative inefficient, as price exceeds marginal costs (P > MC). When goods are produced at 5 units, it is allocative inefficient as marginal costs exceed price (P < MC). It will be allocative efficient when goods are produced at 3 units as P = MC.
Examiner comment

This candidate had a reasoned account of market failure in terms of public goods, merit goods and externalities. There was also an explanation of productive and allocative efficiency. The weakness of this answer was that there was little on the role of government intervention and even less on the application to cars. Both government intervention and an application to cars were required by the question.

Mark awarded = 15 out of 25
Question 3

(a) Discuss whether demand schedules and budget line diagrams are similar in the way they represent the effect of

(i) a rise in the price of a good
(ii) a rise in a consumer's income. [12]

(b) Analyse what is meant by the equi-marginal principle of consumer demand and whether it can be linked to the derivation of a market demand curve. [13]

Mark scheme

(a) A rise in the price of a good: a demand schedule has price and quantity of one good bought against price; budget line diagrams have quantities of two goods – price is not on the axis; one cannot tell how demand will change with budget line unless you also show preference lines.

A rise in a consumer’s income: similarity, both move parallel out for a rise in income; but cannot tell what will be bought unless have supply line – with demand – or preference lines with budget line. [12]

L4 For a sound discussion indicating the similarities/differences [9–12]

L3 For an accurate explanation but with a less clear comparison [7–8]

L2 For a general undeveloped explanation with little comparison. [5–6]

L1 For an answer which has some basic correct facts but includes irrelevancies and errors of theory [1–4]

(b) Analysis of equi-marginal principle which underlies an individual demand curve. The sum of individual demand curves form the market demand curve. Whether individual utilities can be added is debatable. [13]

L4 For a reasoned discussion linked to more than one good and clearly structured answer with a conclusion [9–13]
[Low L4 maximum if there is no mention of market demand]

L3 For a fair discussion but undeveloped answer but still with a conclusion [7–8]

L2 For a limited attempt which does not clearly determine the equilibrium position for more than one good and no conclusion. [5–6]

L1 For an answer which has some basic correct facts but includes irrelevancies. Errors of theory or omissions of analysis will be substantial. [1–4]
3a

Demand schedule is the graphical representation of changes in quantities that consumers would demand or would want to purchase at different prices at a certain period of time. It is used for only one good to represent the demand for only one good.

Budget line is the graphical representation of all possible combinations of two goods that consumers can purchase with their fixed income. It is restricted to be fulfilled by the income they earn and the price of goods. It is important to produce a budget line as in to show how two goods will be purchased.

(i): A rise in price of a good in case of demand schedule lead to show a change in quantity along the curve. As the price rises, consumers would demand the good less as than before. As in Figure in the right, show the demand schedule for for a good, with quantity demanded in the x-axis and price in the y-axis. It is shown that a rise in price from P to P₁ will lead to a fall Q to Q₁. This will be also the same case for budget line as the quantity demand for the good will fall.
as the price rise, however since it is the budget line shows the demand of one good in compare to the other, it would be represent in the same way.

The figure shows, good X is on the x-axis and good Y is in the y-axis.

Before the rise in price for good X, the quantity demanded is Q and after the rise it pivoted at Q and fell to Q'. However, there could also be a rise in quantity demanded.

For good Y as a rise in good X would lead to consumers demanding less of good X and possibly substitute it with good Y.

For both, the demand schedule and budget line the fall in quantity demand of the good that rise in price is because consumer would substitute the good which appear costly to the good which appear cheap in compare this is referred to substitution effect.

(ii) A rise in income for would lead to a change in demand schedule and budget line and as an increase in income would allow consumer to spend more, so they would purchase more of the good. The figure shows a demand curve, with D in x-axis and price in y-axis. Here, the rise in income shifted the curve to left. It means for the same price P, more quantity is demanded, i.e Q1 to Q2.
Similarly in the case of Budget line the curve shifts to left meaning that both can both the good can be purchased more that before without sacrificing the other as there is an increase in Income.

In the diagram the budget line it is shown by an increase in $Qx$ of the good, i.e. $Q_y$ to $Q_y'$, and $Qx$ to $Qx'$ if rose.

This refers to the income effect for both the diagrams, as an increase in income leads to increased disposable income for the consumer.

ii.

Consumers derive a happiness or satisfaction when they consume a good good, it is referred to the utility of a good. Consuming a good. Marginal Utility is the satisfaction derived from the consumption of additional one unit of the good. However, this unit Marginal Utility tends to fall as consumer consumption increases. This is known as diminishing marginal utility. As consumers earns fixed income, they would want to utilise the income in a way that will maximise the utility derived from all the goods consumed with that income.

It is the equimarginal principle of consumer demand, as they and is represented as:

\[
\frac{MU_A}{P_A} = \frac{MU_B}{P_B} = \frac{MU_C}{P_C} = \frac{MU_N}{P_N}
\]

$MU_A$ is the Marginal Utility, $P$ is the price and $A, B, C, N$ are the different goods purchased.
Examiner comment

In section a) this candidate gave a clear explanation of both a demand line and a budget line. Changes in price were demonstrated correctly on both types of curve with a clear comparison. Income changes were correctly shown as indicating a similar movement on both types of curve. In section b) the candidate explained the meaning of the equi-marginal principle and discussed its link to a consumer’s demand. The answer could have been improved if the last part of the question which asked about a market demand curve had been more clearly discussed. Mention was made of a market demand curve but the explanation surrounding this was really related to an individual consumer’s demand curve.

Mark awarded = 22 out of 25
Example candidate response

The demand curve shows the relationship between price and quantity demanded of a product. It is downward sloping as price and demand have an inverse relationship, i.e., if price increases demand decreases and vice versa.

The budget line illustrates the quantity of two goods that a consumer could buy with the amount of given income/resources. For example, if income is $1000 and there are two goods, A and B, which cost $1000 and $200, the budget line would be as follows.
The when there is increase in the price of a good, the will be movement along the demand curve i.e.

As the price increase from $P_1$ to $P_2$, the quantity demanded decrease from $Q_1$ to $Q_2$. However, the degree of change would depend upon the elasticity of demand whereas when price of one good
increases, there will be a partial shift in the budget line e.g. price of good A also becomes $2,000.

Product A

Product B

Previous budget line was AB while new budget line is CB.

Hence the effect of a rise in price is not shown for budget line and demand curve as budget line shifts (partially for one and completely for both) to show an increase in price whereas there is only movement along demand curve.

ii. As the consumer income increases, the demand also increases (curve shifts rightwards). Same is the case for budget lines as there
Income increases, the budget line will shift rightwards.

Effect on demand curve:

Effect on budget line: (Taking the example from part (i) let the prices be £200 for both goods and income increases to £1200)

Product A

However, if other factors also increase simultaneously, the relative effect...
would have to be considered especially in comparing the demand curve. 

It is suggested by some economists that the demand curve actually reflects the marginal utility of a product rather than the total utility. This is why it is downward sloping (as marginal utility decreases as a quantity purchased is increased). This is the diminishing marginal utility theory. It guides the consumer in choosing the amount of a single good that can be maximized. It is the point where marginal utility (MU) is 0, i.e., M = 0.

This theory only guides the consumer regarding the maximization of utility from a single product and does so.
Examiner comment

This candidate gave a clear explanation of the meaning of a demand curve and a budget line in section a). For a price change the shift along a demand line and a pivot about a point on one axis for the budget line were indicated. Income changes were shown as a parallel shift in both the demand and budget lines. This section of the answer could have been improved if there had been more of an explicit comparison between the demand curve changes and the budget line changes. The reader was left to conclude which were similar and which were different. Section b) was a weaker section and although marginal utility was discussed the answer did not really explain the principle of equi-marginal utility and its link to a demand curve.

Mark awarded = 16 out of 25
Example candidate response

(a). A rise in the price of a good does affects the demand schedules and budget line diagrams. From the demand curve in the demand graph, it is clear that the demand curve is move downward, which axis-y is price of a good and axis-x is the quantity of demand. When the price of a good is increasing the demand will will drop. Because then consumers will buy another similar good which is lower price to replace the the the high one with higher price. For example when ice-cream's price increased, the consumers willing to eat yogurt rather than ice-cream which caused ice-cream surplus.

However, a rise in a consumer’s income may affect the demand schedules and budget line diagrams in aggregate demand it calls income distribution effect. It is because the income of consumer increase, it gives the consumers the abilities to demand their needs especially in the labor force.
Examiner comment

This candidate gave a descriptive answer which did not contain any diagrams. In section a) the description of the change in the demand line with respect to a price change was reasonable but there was no real explanation of the change in a budget line due to a price change of a good. The changes caused by an increase in income were not explained. In section b) although there was a reference to the fact that the market demand was an aggregate, there was no explanation of the equi-marginal utility principle of consumer demand.

Mark awarded = 7 out of 25
Question 4

(a) Discuss whether it is always advantageous for a firm to grow in size. [12]

(b) Explain the economic theory of profit maximisation for a firm and consider whether firms are likely to follow this theory in fixing their price and output. [13]

Mark scheme

(a) Discussion of possible reasons for growth including large market demand, economies of scale, possible future profits, with a contrasting comment on reasons why it might not be advantageous to grow in size; diseconomies of scale, small market demand, specialised products/services. Allow a wider interpretation which discusses effects on consumers and in the economy. [12]

L4 For a sound discussion with contrasting explanations. [9–12]

L3 For an accurate explanation but with an emphasis on one side – possibly of economies of scale only. [7–8]

L2 For a general undeveloped explanation. [5–6]

L1 For an answer which has some basic correct facts but includes irrelevancies and errors of theory [1–4]

(b) Explanation of the theory of profit maximisation. Candidates should then consider not only whether it is possible to calculate marginal revenue and marginal cost to achieve profit maximisation but also whether the firm might have alternative aims. Sales maximisation, behavioural, managerial, satisficing, market share aims might be mentioned. [13]

L4 For a reasoned discussion and clearly structured answer with a conclusion [9–13]

L3 For a fair discussion but undeveloped answer mentioning either only one part of the question or both parts but only limited mention of alternative aims, but still with a conclusion [7–8]

L2 For a limited but acceptable attempt to consider the question with very limited development of either part and no conclusion. [5–6]

L1 For an answer which has some basic correct facts but includes irrelevancies. Errors of theory or omissions of analysis will be substantial. [1–4]
Example candidate response

a) Large-scale production is often said to be advantageous for a firm due to the benefits that come with expanding productive capacity. This is not, however, always the case as sometimes growth of a firm may bring about negative effects.

One of the most commonly cited reasons to support growth of a firm is the benefit of gaining economies of scale. This refers to a situation in production where the average cost of production decreases while the output level increases. In figure 1, this is shown from output level Q to Q₁. As output rises, the long-run average cost decreases.

![Graph showing average cost decrease](image)

This can be due to technical economies of scale, where capital and labour are used to achieve their maximum productivity levels, managerial economies of scale which encourages specialisation in job roles and functions and so on. Firms functioning with large-scale production can be said to enjoy lower average costs which is an advantage for firms to engage in price competition as prices can be lowered without losing the profit margins. This is a benefit for consumers, as lower prices would increase spending power. Also, if prices do not fall, then firms with the benefit of economies of scale would be able to gain more profits and would be more likely to gain abnormal profits. This is also a benefit as it enables firms to invest in research and product innovation, providing an advantage in terms of non-price competition that also benefit consumers with better quality.
Economies of scale can generally be seen as an improvement in terms of efficiency as firms' costs are minimized and the use of resources is maximized. In these ways, large-scale production may be advantageous and firms' growth would be positive for the market.

However, this is not always the case at output levels above Q, in figure 1 show diseconomies of scale as firms find it increasingly difficult to manage production beyond a certain level. This decreases efficiency and results in wastage of resources.

Also, firms may become monopolies if growth is allowed to continue without sufficient competition. Monopoly situations can result in consumer exploitation as the lack of substitutes can cause firms to have total market control and raise prices excessively. Monopolies are also likely to be inefficient as the lack of competition reduces the incentive to minimize costs in order to maximize profits. Monopoly situations can result in a lack of choices for consumers and this would be seen as undesirable, especially if consumers lose sovereignty altogether in the market.

Exceptions may occur in the case of natural monopolies, where high sunk costs and costly technology or infrastructure may encourage a firm's growth to cater for the needs of the market. This is because it may be better for the allocation of scarce resources if infrastructure and capital are not duplicated by having many small firms supply the same product.

In conclusion, there are advantages to a firm's expansion of productive capacity, but there may also be disadvantages. It is necessary to examine the market conditions in each situation and the relevant possible effects should be evaluated before determining how advantageous it would be for a firm to grow in size.
b) Profit maximisation refers to a firm's objective to maximise profits in the production of a good or service, obtaining the highest possible profit margin. This is often illustrated as being the most common goal for many private firms. The maximum profits for a firm are obtained at the point where MC = MR, or where firms' marginal cost is equal to the marginal revenue generated by the extra unit produced. At this point, firms are on the verge of making a loss with the next unit of production.

Firms are said to aim for profit maximisation in order to gain more returns for the entrepreneur or shareholders. Also, in some firms, it would be ideal to gain more profits in the hopes of earning abnormal profits that can then be reinvested or used for research and development or innovation purposes. This would then increase a firm's ability to compete in a non-price manner and improve the quality of output or improve the productivity of capital and labour through technological advances and training.

However, not all firms may engage in profit maximisation all of the time, depending on the circumstances of the firm and its position in the market and industry. Particularly for firms that have just entered a market, they may choose to maximise sales instead in order to more firmly establish their position and control of market share. This results in firms settling for a profit margin below the maximum attainable profit level in favour of increasing their clientele or consumer base, possibly through selling lower prices. It is worth noting that firms will rarely go to the point of being unable to sustain variable costs in the short run, indicating that in the long run, profit maximisation may after all be the most commonly pursued objective for a firm. In the case of a new entrant in a market or industry, the firm is less likely to concern itself with profit maximisation if it is a firm that is able to diversify and cross-subsidise its goods. This refers to a firm's ability to sustain losses for the production of a good or service due to its pre-established position and higher profit margins for another good or service, again indicating that to some extent, profit maximisation is likely to play a
Examiner comment

This candidate gave a good response to section a) which contained an explanation of the advantages of growth through economies of scale, the disadvantages caused by diseconomies and the undesirability of some monopolies. Profit maximisation was discussed in section b) but there was also a discussion of alternative aims of a firm including non-price competition, maximisation of sales, increasing market share, cross-subsidisation, satisficing, all of which might need to be balanced against the desire to gain maximum returns for shareholders.

Mark awarded = 19 out of 25
Example candidate response

Firms in an economy can expand through external integration and internal integration. By internal integration, firms can expand by increasing the number of branches in an economy while external integration can be divided into forward integration or backward integration. Forward integration occurs when a firm expand into a different sector of industry, which takes place after its existing sector while backward integration occurs when a firm expand into a sector which is before its initial sector in the industry. For example, Volkswagen and BMW merged into a single company recently.

By expanding, a firm will be able to achieve advantage as well as disadvantage. The most significant advantages of large company is economies of scale. Economies of scale occurs in the long run where firms will be able to produce outputs at minimum cost. In other words, firms will be productive efficient.

Based on the diagram, as a firm expands in size, the firm will be able to produce Q, quantities at P, which is the lowest point of the long run marginal cost graph. When a firm experience economies of scale, various sectors such as financial will be easier to have lower cost to the company. For example, large firms such as Tesco Supermarket will be able to obtain loans or financial aid easier as investors will have high confidence towards the company as the risk bearing of the investors will be lower compared to investing in small retail shop supermarkets.

Advertising specialization can also take place when firms experience economies of scale, hence decreases costs such as time and thus increase productivity of the firms.

Besides that, if a firm is producing at its minimum cost, the profit margin of the firm will increase as its revenue will be higher. The increase in profits earned by the firm can be used for research and development as well as investments to increase the output productivity as well as the quality of the goods and services produced. By doing so, customers will also be able to have a wider range of goods and services to choose.
Furthermore, on the other hand, the increased employment level can also increase due to the increase in output or productivity by the firm. Hence, the national income as well as the gross domestic product of an economy will increase from $G_1$ to $G_2$ as the supply increases from $AS_1$ to $AS_2$.

As firms expand in size, consumer loyalty can also be gained. In other words, the low price of goods and services of the firm can also gain market share in an economy. With the lower price charged on goods and services produced in an economy, consumers will be able to enjoy goods and services at lower prices, hence improving their standard of living in the country. As the firm obtain market share in the industry, less advertising will be needed as consumers loyalty are already obtained. For instance, luxury supercar BMW will not need to advertise as much as previously since it has already gained trust and market share due to its quality and performance.

However, as firms expand, more space will be needed for increased manufacturing in buildings or premises. By doing so, the firm can expand its production and thus increase output. As the output increases, more resources will be used, causing increased pollution and the possibility of depletion of resources. The non-renewable resources such as petroleum cannot be renewed, hence might decrease the availability of these resources for future generations. In other words, sustainable growth cannot be achieved.

Moreover, as a firm grows in size, there can be diseconomies of scale such as problems of coordination or communication. This causes time lag, causing affecting the efficiency of the firm. There might also be alienation of workers as a firm grows, causing demoralization of workers, causing a decrease in productivity.

As firms expand in size, there is a possibility that the firm might act as a monopoly in the market where quantity of goods produced are reduced and the price charged on goods and services increases. This is because due to investment in research and development, the quality of goods produced by the large firm might be of better quality compared to the small retail shops, causing an inelastic demand of goods. With this, the price can be charged higher to obtain higher revenue and profits. Along with this, the small companies which do not enjoy economies of scale might shut down due to price wars with the large firms.
In conclusion, there are disadvantages and advantages that can occur as a firm expands. However, it is able to control the damages or disfigurement of disadvantages by government intervention such as maximum and minimum prices as well as subsidies to infant industries. Quotas on access to resources can also be imposed to maintain sustainable growth in the economy.
Profit maximization for a firm can be achieved when the marginal cost equals the marginal revenue curve. This is because since marginal cost is the difference in additional cost of producing an additional unit, it can be said that it is the supply curve of a firm. Marginal revenue curve is the revenue curve is said to be the additional revenue generated by an increase of a unit of sales of the firm. Hence, it can be taken to be the demand curve of the firm. Marginal revenue curve is downward sloping as the increase in price will generate lower demand by consumers due to substitution effect where consumers will switch to relatively cheaper substitutes.

Hence, firms will produce according to profit maximization to obtain its highest possible revenue. However, it differs for the type of market structure in an economy. In perfect competition market, the firms are price takers; hence the marginal revenue will be perfectly elastic as the price are equal at various outputs. Therefore, the average revenue, marginal revenue curves are the same as price. Based on the graph, MC cuts MR at point P where firms produce at Q, at P and set a price at P1.

In monopoly and monopolistic markets, firms will charge higher price at lower quantity because of the inelastic demand of consumers. Due to product differentiation in monopolistic markets, the marginal revenue and average revenue graph is downward sloping while in monopoly, the inelastic demand due to product differentiation causes the marginal and average revenue graph to be downward sloping. In this case, monopolistic firms and monopoly firms set a higher price hence,

Based on the graph, the MC curve cuts the MR curve at point B, where the quantity produced is Q at P and price charged at P. However, due to inelastic demand and being price setters, the firms charge a higher price at P instead of P to obtain higher revenue, converting consumer surplus at area ABP into revenue.
Examiner comment

This candidate gave a reasonable answer which could have been improved in section a) if there had been further development of economies of scale and/or of the reasons why it might be advantageous for small firms to exist in their own right, rather than concentrating on the lack of managerial control as a firm seeks to grow. An improvement could have been achieved in section b) if there had been further discussion on the alternative policies that a firm might use. Mention was made of contestable markets and predatory pricing but the answer could have been developed with a mention of sales maximisation, behavioural aims or satisficing.

Mark awarded = 15 out of 25
Example candidate response

(a) It may be advantageous if a firm is competing in a perfectly competitive market, where firms achieve abnormal profit as a result of profit maximisation. It may be advantageous if a firm is competing in a perfectly competitive market where profit maximisation, $MC = MR$ occurs.

Since in a perfectly competitive market, $P = MC$, therefore $MC = MR$, so $P = MR$. Price is equal to marginal revenue, means firms achieve short run abnormal profits. This abnormal profit can be directed to R&D, which may innovate the production process resulting the firm to experience economies of scale, where which is reducing average cost as size of firm grows.

![Graph](image)

It may be disadvantageous, as firms achieve abnormal profit, competitors may enter the market, resulting the price to be fall, therefore firm cannot achieve abnormal profit in the long run, but normal profit. Then they may not be able to invest sufficient amount of funds to R&D, and may not experience economies of scale, but possibly possibly diseconomies of scale, as firm grows in size, but they may not find innovative method to reduce average cost.
1. Profit maximisation is a point where MC = MR, as shown in the diagram.

2. In the short run, they achieve abnormal profits, which attract firms to enter the market, this shifts industry supply curve outwards resulting in prices to fall, this continues until firms earning normal profits in the long run. If only normal profits are earned, then firms exit the market, so industry supply curve shifts inwards, again in the long run, firms achieving normal profits only. Therefore as a result, firms maximising profit earns normal profits in the long run.

Firms in oligopoly may collude to generate greater profits, fixing price at which abnormal profits are generated and give quotas to each firm. But this may be break up easily, if one firm cheat to generate even greater profits by exceeding production quotas and charging higher price.
Examiner comment

This candidate began the answer to part a) by explaining profit maximising in perfect competition and only briefly mentioned diseconomies of scale. Some of this information was repeated for section b). The diagram in section b) lacked the correct labels and although there was a brief mention of oligopoly there was no real explanation of the theory of profit maximisation and no discussion of alternative aims which a firm might follow.

Mark awarded = 8 out of 25

Question 5

In imperfect competition, labour markets can lead to worker exploitation in terms of the wage rates they receive compared with wage rates in perfect competition. Discuss this opinion.  

Mark scheme

Candidates should explain the economic theory of wage determination (marginal revenue product) and compare the situation in perfect and imperfect competition. The theory indicates that wages are lower in an imperfect labour market especially if there is monopsony. The extent of the reduction varies depending on whether the labour market is considered with a perfect or imperfect product market. However, the comparative reduction in wage rates may be corrected, at least in part, by the strength of unions or by government legislation.

L4 For a thorough explanation of the analysis of wage determination with a clear comparison of the two markets and a comment on trade unions and/or government policy. [18–25]  
(14–17 for demand and supply only with institutional factors and/or government policy)

L3 For a competent explanation of the two markets but with a limited discussion and application. [14–17]  
(10–13 for demand and supply)

L2 For a correct but undeveloped explanation with only brief application [10–13]  
(6–9 for demand and supply)

L1 For an answer which contains inaccuracies and only a few correct points [1–9]  
(1–5 for demand and supply only)
Example candidate response

Whether labour markets under imperfect competition lead to worker exploitation in terms of wage rates they receive compared to wages in perfect competition is highly subjective and dependent on an analysis of the presence of a monopolist, trade unions and government intervention in an imperfect market.

Firstly, under perfect competition, the MRP theory best explains how wages are determined in the market. Here, the wages of workers are dependent on their Marginal Revenue Product (MRP). MRP, in essence, is the amount of additional revenue a firm would earn by employing an additional unit of worker. Since firms under perfect competition are profit maximisers, firms will hire workers up to the point where MRP is equivalent to the marginal cost of labour (MCL), as illustrated in the graph below. [Graph 2]

Since under perfect competition buyers (firms) and sellers (workers) are price takers, the wage rate is set by the interaction of demand and supply in the market. The reason that the graph for the individual firm is represented is to distinguish between perfect and imperfect competition. It is assumed that under perfect competition, all workers are homogeneous. Hence, the cost of hiring an additional unit of worker to the firm is constant. There is no exploitation of workers in terms of wage rate under perfect competition as a firm who offers a wage rate lower than the market rate would have no workers wanting to work for them given the unlimited buyers (other firms) who offer the market wage.
There are several reasons as to why there could be exploitation in terms of wage rate under imperfect competition. In the presence of a monopolist, wages are often much lower than what they would have been under perfect competition. This is because a monopolist has an upward sloping supply curve and even steeper marginal cost of labour curve. The reason for this is that a monopolist would have to increase the current wage rate in order to attract more labour into the market.

To add a definition, a monopsony exists when there is only a single buyer in the market. This is illustrated by the diagram below:

Being a profit maximiser, a monopsony would hire workers up to the point where MCL = MRP. As observed from the diagram above, workers are paid a much lower wage rate (W₁) than the market equilibrium (Wₑ). Hence, one might conclude that under a monopsony, workers are indeed exploited and paid lower wages. The reason a monopsony is able to do so is because that since it is the sole buyer of labour in the market, workers have no choice but to accept the lower wage rate.

Conditions however, are not too dire when a trade union enters the picture. Trade unions (another key characteristic of imperfect labour markets) serve the purpose of collectively representing workers in negotiating wage rates with employers. This is because collective bargaining power exerts a significantly large amount of influence than the individual.
Bargaining with an employer can. The entrance of a trade union in a situation of monopoly is as illustrated below.

Diagram 4

Here, the trade union has successfully negotiated a higher wage rate for workers than the monopsonist had initially offered. Hence, the wage rate the monopsonist offered (\(W_m\)) has now increased to \(W_u\). In this instance, the trade union had negotiated a wage rate equivalent to the market equilibrium. However, a trade union with higher bargaining power would be able to demand an even higher wage rate. This would depend on factors like the union density and substitutability of labour. In essence, though, we might derive from here that it is possible for wage rates to be higher than the market equilibrium (and hence perfect competition) under circumstances of imperfect competition.

Intermediately, we can conclude that a monopsony drives wages lower than what they would be under perfect competition. However, with the presence of a trade union, wages could potentially be much higher.

Besides this, there is no government intervention under perfect competition. Imperfect competition, on the other hand, may evoke government legislation such as minimum wage requirements that could drive up wages. This is illustrated in the graph that follows.
Examiner comment

This candidate gave a very clear explanation of the determination of wages in perfect competition through the market demand and supply. This analysis was then contrasted with that which applies to imperfect competition. A discussion of the influence and power of a monopsonist, a trade union and a minimum wage determined by a government then followed. A concluding paragraph drew attention to the difference that may occur between perfect and imperfect markets when trade unions and minimum wage regulations exist.

Mark awarded = 21 out of 25
Labour is derived demand. An increase in the demand for property houses will lead to an increase in property development. Thus, this will lead to an increase in the demand for construction workers.

Marginal revenue product (MRP) is used to indicate the demand for labour. MRP is obtained by multiplying marginal physical product with marginal revenue. (MRP = MPP x MR). MPP is the additional output produced by employing an additional worker. MR is the additional generated by employing an additional worker. MRP is known as the additional revenue of a product produced by employing an additional worker.

There are assumptions for MRP. There are perfect and imperfect in goods market and factor market. All variable perfect in the goods market indicates that the demand for labour is a horizontal line where DD = P = MR = AR. Imperfect in the goods market indicates that the demand for labour is downward sloping. All variable factors are homogenous. It is due to the law of diminishing marginal return. Firms are set to operate in order to achieve maximum profit.

Wages are determined where MRP = MFC. MFC is the additional cost of employing an additional worker. The diagram below shows wage determination in the perfect market.

The supply curve of the labour is horizontal as labour and firms both have perfect knowledge. The equilibrium is where wages are at W₀ and quantity of labour is at Q₀. Point A cannot be the equilibrium point as MRP continues to rise. When MRP > MFC, firms will employ more workers until it reaches an amount of Q₀ labours.
The diagram below shows the imperfect wage determination in the imperfect market.

The supply curve of labour is upward sloping as both labourers and firms have imperfect knowledge. Wage is determined where \( MFC = MRP \), which is where wages are at \( W_2 \). However, firms do not have to pay \( W_2 \) to get \( Q_0 \) amount of labour. It only needs to pay the labour at \( W_1 \). This is due to the imperfect knowledge of the workers on the availability and types of jobs. Workers are being exploited as they should be paid at \( W_2 \) but instead are being paid at \( W_1 \). This is due to the fact that in an imperfect market, monopsonist are the price setters.

When there is exploitation of workers, there will be the presence of trade union and government. Trade union will help workers to talk terms with the firm in order to increase their wages.

The diagram above shows the difference in wages when there is a presence of trade union. Without trade union, wages of labour are at \( W \), whereas wages of labour are at \( W_2 \) without trade union. Trade union will also help labourers seek for working benefits such as medical benefits and overtime pay.

Government intervene by setting minimum wages of the labour. This will allow a decrease in employment of \( Q_0\) to \( Q_1 \).
Examiner comment

This candidate gave an explanation of the analysis involving marginal revenue product theory but with less development than is required for a very good answer. For example, the candidate did not clearly indicate how the wage which was used by a firm in perfect competition was determined by the demand and supply in the market.

Mark awarded = 17 out of 25
Example candidate response

In imperfect competition, which may manifest itself in the form of monopolistic competition, oligopoly, monopoly, or monopsony, the notion of fair wages is often debated because even imperfect markets are thought to distort wage determination and exploit workers.

The comparison may be held between a perfectly competitive market structure and a monopsony monopsony, as well as a monopoly.

A monopsony is essentially a monopoly buyer of labour. It is one buyer for many sellers which is why the supply in a monopsony for labour is significantly more inelastic than that of the supply in a perfectly competitive labour market. This means that, while equilibrium wage is at $W_1$, a monopsony, being profit maximizing, may hire workers at $W_1$ without an incredible decrease in output whereas in perfect competition, where demand is equal to the marginal revenue product of a worker, a wage decrease would result in a great loss of output, which will stop firms from
Reducing wages. This ensures that wages in a perfectly competitive market do not exploit the workers, as they are determined by the demand and supply for labour. A monopsony, however, must also be careful with its wage setting power, as if its wage rates go below the transfer earnings level of wage for too many workers, the amount of workers available to the firm will sharply decline. In imperfect competition, there is also the presence of discrimination and imperfect knowledge, or asymmetric information between the employer and worker, which leads to the exploitation of workers because they are not given the opportunities their MRP requires without discrimination against female employees, for example, employers may pay them lower wages than men in the same occupation. This is not possible in a perfectly competitive market where there is no discrimination and perfect knowledge, as well as occupational mobility/geographical mobility.

Monopsonies as labourers often have no choice but to work at lower wage rates as their skills are not transferable or they are not able to move to a location with more opportunities. There are all kinds of imperfect market competition which distort wage rates and exploit workers. Workers may also be exploited if their wages are below the real wage rate so that they operate under a “money illusion”.

In a monopsony and a monopoly, labour is not paid the wage rate equal to marginal revenue product. In the imperfect competition in such market structure, there is the equity of perfect competition which ensures fair wages so the opinion is largely correct, if somewhat inevitably. Firms in oligopolies, duopolies, and monopolies, with wage setting power, do not seek to retain fairness amongst their workers.
Examiner comment
This candidate gave a descriptive answer. The diagrams were not clearly labelled and there was confusion between perfect and imperfect competition. There was only passing reference to marginal revenue productivity, the analysis of which was omitted, no reference to trade unions nor to government intervention in the form of minimum wage legislation or regulation.

Mark awarded = 10 out of 25

Question 6

(a) An increase in investment will raise national income but an increase in the desire by consumers to save will reduce national income.

Explain why this is the case. [12]

(b) To increase national income, interest rates should be lowered; indeed lowering interest rates is the only policy available to increase national income.

Discuss whether you support this opinion. [13]

Mark scheme

(a) Candidates should explain the different effects of an injection of investment and a withdrawal through saving by use of the multiplier process. Possible use of ‘paradox’ of thrift idea. [12]

L4 For a sound explanation with good application and a clear understanding of the principles involved. [9–12]

L3 For an accurate explanation of the multiplier but with a more limited contrast of the difference between the investment and saving. [7–8]

L2 For a general explanation probably in descriptive form. [5–6]

[Maximum L2 if there is no mention of the multiplier]

L1 For an answer which has some basic correct facts but includes irrelevancies and errors of theory [1–4]

(b) Candidates should analyse how lowering interest rates might help increase national income through increased investment or increased spending and then discuss whether lowering interest rates is the only policy available. [13]

L4 For a sound discussion with good explanation of the analysis of interest rate changes and a consideration of alternative fiscal measures with a conclusion [9–13]

L3 For a competent comment but with limited development of the analysis or undeveloped alternative policies and a weaker conclusion. [7–8]

L For a brief explanation and with a weak discussion of interest rates or weak alternative policy measures with no conclusion. [5–6]

L1 For an answer which has some basic correct facts but includes irrelevancies. Errors of theory or omissions of analysis will be substantial [1–4]
Example candidate response

Consumption and investments are two important components in measuring the national income of an economy. These two components are part of the aggregate expenditure of an economy and contribute to the gross domestic product (GDP). The circular flow of income indicates that a change in consumption and investments can cause a change in national income due to change in aggregate expenditure. This can be proven by the formula

$$AE = C + I + G + (X - M)$$

where $C$ is consumption, $I$ is investments, $G$ is government spending, $X$ is exports and $M$ is imports.

We can show the changes in national income due to investments by drawing diagrams as well as including the multiplier effects. Investments are spending made by firms in a certain capital so that the firms would be able to produce a larger quantity of goods and services in the future. For example, a firm invests in a plot of land to build a factory so that production can be increased. Investments consist of autonomous investment $I$ and induced investment $I_e$. Investments are usually fixed in volume so the change in investments would cause the aggregate expenditure (AE) curve to shift upwards.

In the diagram, an increase in investments would cause the AE curve to shift from $AE_n$ to $AE$. As a result, national income would increase from $Y_n$ to $Y_1$. We can note that the increase in $Y_1$ is larger than the increase in aggregate expenditure. This is due to the multiplier effect which states that a small change in aggregate expenditure leads to a larger change in national income. This can be represented by $\Delta Y = k \Delta AE$ where $k$ is the multiplier and $k > 1$.

$\Delta Y = k \Delta AE$

$\frac{\Delta Y}{\Delta AE} = k$

MPS is the marginal propensity to save, MPM is the marginal propensity to import and MPT is the marginal propensity to tax. Therefore, an increase in investments would cause a larger increase in national income.
On the other hand, an increase in savings would cause national income to decrease. To understand this, we must note that saving is the alternate option to consuming and at a fixed income, if consumption decreases as savings increase, \( MPS + MPC = 1 \). A desire to save by consumers causes the MPC (marginal propensity to consume) of consumers to decrease. This causes the gradient/slope of the AE curve to become more shallow since the MPC represents the gradient of the AE curve.

When consumption decreases, the AE curve would shift from \( AE_0 \) to \( AE_1 \), downwards. The result is that national income would decrease from \( Y_0 \) to \( Y_1 \). Again, we must note that the multiplier effect takes place when this happens as the decrease in national income (\( \Delta Y \)) is significantly larger than the decrease in aggregate expenditure (\( \Delta AE \)).

As we can see, changes in components of the aggregate expenditure can lead to a larger change in the national income. Hence, economists and governments can implement policies to contract or expand the economy using the effect of the multiplier when necessary. However, the multiplier value is different for every economy and it is not easily measured in reality. Furthermore, there is a possibility that the multiplier value is less than one, making policies inefficient. Therefore, research must be done before policies to contract or expand the economy can be carried out.
Keynesian economists stress upon the importance of interest rates in an economy. Interest rates are crucial in the money market as well as the goods market as it determines the money supply in an economy as well as the number of investments made, both of which are factors influencing national income. There have been arguments about whether controlling the interest rate is the best way to increase national income.

The effect of lowering the interest rates to increase national income can be explained using the monetary market transmission mechanism. In a money market, interest rates are determined by the demand and supply of money. Suppose the central bank increases the money supply, this would cause a rightward shift of the money supply curve, causing the interest rate to decrease.

The money supply increases from $S_m$ to $S_m'$, causing the interest rate to decrease from $r_0$ to $r_1$.

Interest rates are the most important factor influencing investments. This is because firms wanting to invest would require large amounts of capital and would need to borrow these funds from banks. If the interest rate were high, there would be less incentive for firms to borrow as they would have to pay back more. A fall in interest rates would prompt investments by firms.

In the diagram, $MBC$ is the marginal efficiency of capital. When interest rates decrease from $r_0$ to $r_1$, the $MBC$ value of investments made would increase from $I_0$ to $I_1$, as firms tend to invest more.

Investments are a part of the aggregate expenditure. An increase in investments would cause an increase in aggregate expenditure and with the aid of the multiplier...
134 Cambridge International AS and A Level Economics 9708

In the diagram, when investments increase, aggregate expenditure would increase from $AE_0$ to $AE_1$. This would result in a significantly larger increase in national income ($Y_0$ to $Y_1$) due to the multiplier effect.

Indeed, the reduction of interest rates would increase national income, and also promote growth. However, a reduction in interest rates can also result in inflation. This is because the aggregate demand in an economy would increase without the aggregate supply shifting.

In the diagram, when aggregate demand increases from $AD_0$ to $AD_1$, at constant prices, the national income increases from $Y_0$ to $Y_1$, but the general price level increases from $P_0$ to $P_1$. This signals inflation. If this were to happen in the long run, there could be hyperinflation as the aggregate supply is stagnant.

Besides that, the action of reducing interest rates would be ineffective if the liquidity trap was operative. The liquidity trap occurs when the demand for money is horizontal, thus changing increasing the money supply would not cause the interest rate to decrease. The liquidity trap occurs during times of strife such as natural disasters and large scale war happening or during a recession such as the Great Depression.

The diagram shows the liquidity trap. Although the money supply has been increased from $M_s_0$ to $M_s_1$, the interest rate remains unchanged at $r$. Investments would not increase and national income would not either.
Examiner comment

This candidate gave a clear and reasoned account of the process of the multiplier in section a) with a conclusion on how an increase in investment or an increase in savings might affect the level of national income. There was a good account in section b) of the link between a change in interest rates and a change in investment. The weakness of the answer in section b) was that although the candidate began the final paragraph with the words ‘in conclusion’, the paragraph was really a very brief list of possible alternative policies to the use of interest rates. No development of these policies was given. The candidate did not, therefore, develop the answer to deal with the second part of the quotation in the question nor did the candidate draw a conclusion about the argument presented in the question. Overall, however, this was still a good answer.

Mark awarded = 18 out of 25
Example candidate response

An increase in investment would mean by the government or firm refers to an injection of money into the economy. When, for example, a firm invests, it hires more factors of production. One main factor of production it hires would be labour. As a firm hires more labour, employment in the industry increases, causing increases in disposable income of the workers in the industry. According to the theory of the multiplier, the proportion of income received would be spent on consumer goods by the consumer worker. This spending would then become income for another firm/worker, and the proportion they spend on goods/services would become income for another person. The multiplier therefore refers to the number of times money is used in an economy. To calculate the value of the multiplier, we use the formula:

$$\frac{1}{1 - MPC}$$

$MPC = marginal propensity to consume$, i.e. the proportion of money spent on an extra dollar earned by a person. An injection, therefore, adds to the circular flow of income between households and firms. An increase in income would normally lower the value in injections, and therefore incomes, would normally lower the value of the marginal MPC, as more income is earned. While the proportion spent on an extra dollar earned would fall, when the value of the MPC falls, the value of the multiplier increases. This causes the number. This means that the extra $100 earned by workers of a particular industry would have a much larger effect on the income within the economy, as money is rolled over more times. This causes an increase in real national income.

On the contrary, the desire for a consumer to save refers to a withdrawal from the circular flow of income between households and firms. This withdrawal causes money to be lost from the economy, as it is not spent on goods and
The marginal propensity to save \((1 - MPS)\) refers to the proportion of money an individual saves for an extra dollar earned. An increase in the marginal propensity to save \((MPS)\) would decrease the value of the multiplier, hence \(\frac{1}{MPS}\). A decrease in the multiplier value would mean that money is not being used as many times, due to households saving a larger proportion. This causes a decrease in real national incomes because less people are receiving portions of the extra income earned, and therefore will face lower income.

b. Interest rates can be used to increase national income. This is because a fall in interest rates would lower the cost of borrowing for consumers and firms. Consumers would benefit from cheaper loans and cheaper mortgage repayments which would increase their discretionary income (less money needed to pay for mortgages). Households will become more attracted to spending than to saving, as savings would not give good returns and therefore leads to a higher opportunity cost. This increases the people to earn more when firms can borrow more cheaply, they are more likely to invest. As interest investment would lead to increased real national income, as mentioned in question A. Both increases in consumer spending and increase in investment would contribute to higher levels of aggregate demand.
The increase in investment can be shown via the marginal efficiency of capital diagram, where as interest rates fall from \( r_0 \) to \( r_1 \), investment increases from \( I_0 \) to \( I_1 \).

The increase in aggregate demand would lead to a move along the short-run aggregate supply curve. Real national incomes would increase from \( N_Y_0 \) to \( N_Y_1 \).

Although the lowering of interest rates could have the potential of increasing aggregate demand and therefore real national incomes, there are also other policies that would also lead to increases in national incomes.

An example could be a discretionary fiscal policy, where spending taxes are reduced and government benefits and investment increases. Given that a high tax rate reduces a worker's marginal tax, the removal of taxes would allow for increased discretionary income, and therefore consumer demand for goods and services would increase. The increased government spending would also produce income for certain census workers in certain industries, for example infrastructure. The multiplier effect would then allow real national income to increase, as these workers spend their marginal income. A discretionary fiscal policy would therefore also shift aggregate demand outwards and cause
Examiner comment

This candidate gave a correct response to both sections of the question. The weakness of the answer was not that it was incorrect but that it lacked development and discussion. Section a) could have given a fuller explanation of the multiplier process and section b) could have dealt more with alternative policies to interest rate changes.

Question 7

(a) As an economy develops, the relative importance of different sectors of production changes. Explain, with examples, why the pattern of employment might change as an economy develops. [12]

(b) Discuss whether increases in economic growth are necessarily beneficial to an economy. [13]

Mark scheme

(a) The usual division of production is into primary, secondary and tertiary sectors. Developing economies move from a dependence on the agricultural sector through industrialisation. Along with this there is a growth in the service sector—industries relying on IT, call centres, tourism. The changes reflect changes in demand, income, urbanisation, government policy, comparative advantage and competitiveness.

L4 For a clear explanation of why the relative importance of the productive sectors of the economy might change with good illustration or examples [9–12]

L3 For a less developed explanation with fewer examples [7–8]

L2 For a more general descriptive account with lack of comment on the causes of the change and with few examples [5–6]

L1 For an answer which has some basic correct facts but includes irrelevancies. Errors of theory or omissions of analysis will be substantial [1–4]

(b) Economic growth involves greater production measured by changes in GDP/GNP. This could cause an increase in the standard of living, improved health, education and employment opportunities. There may be disadvantages. Poor working conditions, the growth of externalities, the careless depletion of resources. There may also still be questions of inequality in the distribution of income or whether the increased GDP is spent on things which might not give direct benefit e.g. military research.

L4 For a discussion of the overall effect of growth on development presenting both positive and negative aspects with a conclusion [9–13]

L3 For an analysis of the contribution of growth to development but with a concentration on either the positive or the negative aspects with a conclusion [7–8]

L2 For a more descriptive account without much evaluation and without a conclusion [5–6]

L1 For an answer which has some basic correct facts but includes irrelevancies. Errors of theory or omissions of analysis will be substantial [1–4]
As an economy develops, the economy is more prone to encounter economic growth and become an emerging economy. When a developing economy encounters economic development, it starts moving towards developed economies by experiencing the same benefits as higher GDP, higher standard of living, and better life. When an economy grows, the relative importance of different sectors like the primary, secondary, and tertiary sector involvement will change.

An newly developed economy in the phase of development will start to focus more attention on its tertiary sector, with relatively more focus on services. Focus on manufacturing sector and very less importance on the primary sector. This is because the economy feels it is better off and people start to consider the primary sector as an inferior one with manual occupations, such as fishermen, gardening, and others. The primary sector is more likely to become mechanized with modern equipment like cranes in sugar cane fields and large fishing vessels to reduce labour.

Secondly, in the manufacturing sector, more importance is given to capital-intensive production rather than labour-intensive. More capitalization and automation is likely to benefit all. Also, when the economy develops more, foreign investors like multinational companies come to invest and set up huge
Manufacturing firms to produce for local market and thereby for exportation. Thus, Coca-Cola setting up plant and machinery in Mauritius has benefited many locals in terms of jobs. Also, these foreign firms along with foreign direct investment bring their expertise which makes the host economy more efficient. This is likely to increase the exportation causing a balance of payment surplus.

Thirdly, employment in the tertiary sector in terms of doctors, accountants and other white-collar jobs increases. This is because improvement in an economy in terms of human capital in the field of education and polytechnique institutes makes the local citizens literate. They prefer to get employed in these service sectors because of higher pay, less manual and physical effort and less risk to life. This can be shown as follows:

<table>
<thead>
<tr>
<th>Employment of Employees (%)</th>
<th>Primary</th>
<th>Secondary</th>
<th>Tertiary</th>
</tr>
</thead>
<tbody>
<tr>
<td>Developed Country</td>
<td>Less developed</td>
<td>Territory</td>
<td>Developed</td>
</tr>
</tbody>
</table>
| Developed Country, experiencing development, will approach figure 2 in terms of its different sectors.

10
Economic growth is a very complex phenomenon which cannot be brought down to a single definition easily by economists. Some economists describe economic growth as an increase in the real per capita income of the citizens of an economy, usually accompanied by an improvement in net welfare. According to Pigou, economic growth has much to do with human endowment, social factors, political factors and history. Additionally, economic growth is shown by an outward shift in the production possibilities curve of an economy. Increase in economic growth is not an unmixed blessing, and there both its positive and negative aspects of an economy.

To begin, an increase in economic growth means the population is better off and is earning higher income. Thus, they will demand more goods and services to enjoy a higher standard of living. Therefore, the economy has to increase production to satisfy the quests of the consumers who to cope with the increase in aggregate demand, more workers have to be employed. A rise in employment which reduces the burden of unemployment by having to provide for unemployment benefits. However, for example in countries like economic growth has been cause by a rise in the use of technology in textile industries and therefore there is non-existing jobs. This as been termed by economists as the "catalytic cracker syndrome."

Cambridge International AS and A Level Economics 9708
Furthermore, an increase in economic growth is beneficial as when more people are employed, they are more liable to pay taxes. Thus, the tax revenue of the government increases enabling it to finance more projects and increase economic development in terms of infrastructure. However, if the government increases the tax threshold, less tax revenue will be obtained.

Increases in economic growth are beneficial as people enjoy a higher standard of living. There is less stressful life as more facilities are available for their leisure time. Also, economic growth certainly that the economy is a favourable place for potential investment. Thus, foreign investors will be attracted to bring Foreign Direct Investment because of business optimism prevailing in the economy. This further improves national income.
Economic growth may reduce the unemployment in the country. A rise in economic growth also leads to a rise in the demand for goods which in turn reduces the unemployment rates. However, economic growth may lead to higher costs of living, especially in countries like India where the middle-class population can be affected. The country's production capacity may not be able to meet the increasing demand for goods, leading to higher prices.

In conclusion, economic growth can have both positive and negative effects. While it can lead to increased income and higher standards of living, it can also lead to higher costs of living and inequality. Therefore, it is important to carefully consider the potential impacts of economic growth when making decisions about economic policies.
Examiner comment
This candidate gave a clear explanation in section a) of the differing importance of the industrial sectors as an economy develops and consumers’ expenditure and job aspirations change. In section b) the candidate gave a well-structured answer. It began with the beneficial changes caused by economic growth but this was balanced by a consideration of the drawbacks of economic growth in terms of pollution, changes in income distribution and changes in health, and possible discontent in the population because the economic growth had been fuelled by the production of capital goods which the population did not use.

Example candidate response

(a) The sectors of production involves primary, secondary and tertiary sectors. Primary sectors are majorly agriculture production or raw material mining. Secondary sectors involves manufacturing machinery manufactory. The tertiary sectors are considered as services sector.

A When economy was not developed, the country is majorly rely on primary sectors, with only few secondary, but almost no service sectors, because they have limited capital input to operate machines or services. As economy develops, the amount of capital available increase, they no longer have to rely on their primary sectors, because land and labour are not the only factors of production they have. So the amount of primary sectors contribute to overall economy will be lower.

In short run, the manufacturing sectors will increase their contribution as they have more capital input, but in long run, it will move to the service sector, because they can purchase the primary or secondary product from abroad, but improves the goods and services within the country, to improve the living standard. Also there is a forth sector where it is for technology developing, a better technology can improve the economy growth.

The example of this is between USA and Africa. USA is a well developed country while Africa is not well developed. USA often buy the raw materials such as diamond, iron, or other resources from Africa.
which is in the primary sector. But the service provided in USA is super excellent compared to Africa. The reason for changes in employment patterns are usually because of people wanting a better living standard, and also a safe and easy job. Raw material mining or other primary sector’s jobs are very tiring and have a risk of dangerous. Also in the service sector requires high education and good skills, which is only able to generate very well in developed countries.

(b) Economic growth is the long term expansion of productive capacity in an economy. The rate of economic growth is measured in increasing in real GDP. It can be shown on PPF and Long Run AS curve. Aggregate Supply curve.

The economic growth results in shift out in PPF and shift out in LRAS. It has a lot of benefits. Firstly, people are having better living standard because of higher income and better service provided. For example: the increased health care is able to longer people’s life expectancy. Also during economic growth, consumers are having high confidence, therefore consumption and investment will
increase which lead to increase in national income. The technology will also improve in order make better quality product or better infrastructure to make people’s life easier and more enjoyable.

However, there are some drawbacks. First of all, the environmental concern. The resources are running out because of higher production, more pollution and waste created which can affect people’s health. Also the extinction of species because of increasing deforestation and lead to animals become homeless.

Secondary, economic growth can result in more income inequalities because most of increasing GDP is resulted by rich people, while poor people remain poor. It could cause a lot of social problems such as crime. Last but not the least, from the Phillips curve, we can know that economic growth cause inflation, the graph is shown below:

![Inflation Graph]

The economic growth will result in less unemployment, so people’s average income will increase, so lead to higher AD. Business will facing an increasing pressure on wage, therefore they will pass the cost to consumers. All the firm also want to increase their profit margin, so they will rise the price.

In conclusion, economic growth is necessarily beneficial to an economy, but the several negative effects should not be
Examiner comment

This candidate referred to the change in the importance of the proportion of people employed in different industrial sectors in section a) and considered some of the possible advantages and drawbacks of economic growth in section b). The weakness of the answer was that both sections, although correct, lacked development with either further explanation or discussion.

Mark awarded = 14 out of 25
7a) The development of an economy can lead to changes in its structure in terms of goods and services produced as well as the growth and contraction of different sectors. This can cause the employment rates in an economy to change drastically. Whatever the case of economic development, unemployment is avoidable, as there will definitely be some people who will be unemployed.

As the structure of an economy changes, the importance of different sectors in an economy changes as well. However, in these changes, the mobility of labour cannot possibly keep up with this change as mobility depends largely on human capital and human capital takes time to be instilled. As a result, many labourers who are unfamiliar with the change in economic structure would find themselves unable to contribute and lose out their work. This is known as structural unemployment. The Industrial Revolution in Great Britain is a classic example of this. As the country moved from dependence on agriculture to manufacturing, farmers began to become unemployed as they were not familiar with the processes of the manufacturing industry. This resulted in a period of time where there was large-scale unemployment. Fortunately, this form of unemployment can be overcome if people are willing to increase human capital by undergoing training and education.

The growth of an economy is not as smooth as we would like it to be. There are times when an economy experiences a huge expansion (boom) and times when the economy faces recession. This instability of the economy cause the employment trend to follow it. During the times where the economy experiences a boom, there is very little unemployment. However, during the recession, unemployment would be very high. This is known as cyclical employment. An example of this is the financial crisis in 2008 where a large number of people in the United States faced unemployment. Since then, employment rates have been improving with the recovery of the economy.
In conclusion, the pattern of growth of an economy very much affects the state of employment in an economy. Since one of the macroeconomic goals is to achieve full employment, the presence of unemployment is seen to be a scourge in the economy. Unfortunately, it is impossible to achieve full employment in an economy, but the right policies can bring the employment rate close enough to full employment.
Economic growth is probably the most important of all the economic goals of the macroeconomy. Growth is seen as a prestigious thing in the eyes of all governments. To economists, growth is the increase in the national income of overall standard of living in a country. There are many benefits of economic growth to an economy.

Economic growth indicates a higher standard of living of a country's population. Since economic growth is indicated as the increase in gross domestic product (GDP) of a country, it also means that the GDP per capita of the economy is higher, indicating that the population is better off due to an increase in real income. However, the population is able to purchase more goods and services. However, the usage of economic growth as an indicator of the standard of living is a flawed method because it does not take into account the income distribution gap between the rich and poor. India for example has one of the highest GDP's in the world. However, the income gap between India's rich and poor is very large. The GDP here growth therefore does not necessarily mean a higher standard of living. A better measurement is the Human Development Index.

Economic growth also promotes employment in an economy. As an economy grows, different sectors of the economy would expand and diversify as well. This would create job opportunities for the population and hence increase the employment rate. However, the increase in employment and growth conflicts with the objective to keep inflation low. As employment and inflation have an inverse relationship. It is not possible to have low inflation rates and yet have high employment rates as well.

Economic growth can also boost the competitiveness of an economy internationally. With growth, more money can be invested into research and development to produce goods and services at a lower cost. This would enable countries to sell and export these goods at lower prices, allowing countries to export more and thus improve the balance of trade of that country. However, this could also...
Examiner comment

This candidate gave a relatively undeveloped answer to section a) which dealt with structural and cyclical unemployment. Although mention was made of a shift between sectors in the industrial revolution in Great Britain the idea of a change in the relative importance of different sectors as a country develops was not elaborated. The answer to section b) had a good structure to it; both the advantages and disadvantages of economic growth were mentioned. The weakness of the answer was that these changes were not developed nor discussed at any length. This was a pity as there was a clear attempt to balance one side of the argument about economic growth against the other.
